Company doctors, mine operators and labor officials have a joint responsibility in the carrying out of a comprehensive program of industrial health and preventive medicine. There is much that each group can do on its own, but on the medical profession falls the responsibility of inciting the three to the need for industrial health work in mining communities. The promotion of industrial health is not an easy task. Above all, public education in public health matters is essential, for only through widespread understanding of such matters can private practitioners as well as public agencies be supported in measures which science and technology have proved to be wise and beneficial.

The public has no true concept of the magnificent role the medical profession plays in their lives. Medicine is a profession which engenders pride in the practitioner. It is a profession which has been ready to meet every challenge. When the statistics on selective service were published, showing that in the early part of the war 54 per cent of America's young men, according to the standards then adopted, were not fitted for military service in time of the nation's greatest need, the medical profession took the lead in urging the public to drop their complacency and to show, instead, concern over the health of the nation.

The situation in the coal mining industry, though confined to a limited but important segment of the American people, presents another challenge to the medical profession as researchers, educators, healers and leaders. That the medical profession will accept the challenge to elevate the standards of health of the 400,000 miners and their families can readily be vouchsafed. By doing so the profession can contribute inestimably to the raising of the health standards of the nation.

NEW HORIZONS IN INDUSTRIAL HEALTH AND WELFARE

ROLE OF MANAGEMENT IN MEDICAL PLANS

ANDREW FLETCHER
Executive Vice President, St. Joseph Lead Company
President, Industrial Hygiene Foundation
New York

The assigned title is so general and the horizons are so broad that I will confine the "horizon" to the point of view of management in reference to increased participation in health and medical plans, with special reference to the thought that industrial health is likely to be a factor in collective bargaining in the future.

I should emphasize at the outset that the Industrial Hygiene Foundation is basically a nonprofit research organization supported by about three hundred industrial companies for the advancement of employee health; its function is solely to find facts and disseminate such information, based on facts, to management, labor and government. As a representative of the foundation I should not and could not express a view on the rather controversial subject assigned me. I cannot speak for "all" industry, as each has its own problems and point of view which are influenced by local conditions. The thoughts which I will outline are solely those of an individual who has always been vitally interested in the improvement of industrial health, the lessening of accident hazards and the development of a satisfactory basis of mutual respect between employer and employee. The St. Joseph Lead Company, with which I am associated, is the largest miner of lead in the United States and one of the major zinc metal and oxide producers. This company thoroughly realizes from its own experience, over a long period of years, that dollars invested in improved working and living conditions pay large dividends in dollars as well as in human happiness.

As good health is the most important asset in life, the development of healthful conditions should be the one common meeting ground of agreement between management and labor. Health should not be a subject to be pulled apart, shoved around and bargained about. Of course, there may be differences of opinion in the procedure and technics employed in approaching the goal of maintaining the health of workers and in the method of increasing the ultimate profit of the employer by improved working and living conditions. Such matters are doubtlessly appropriate subjects for discussions between the interested parties, but I emphasize that technics are but tools. If an employer fails to remedy a hazard or a menace which contributes to poor working conditions, this constitutes a legitimate grievance. It should not be necessary, however, nor is it desirable, that fundamentals of health maintenance become matters of collective bargaining any more than should the principles of management and engineering.

1944	996,368
1945	944,749
1946 (26 weeks)	472,017

SICK LEAVE WITH PAY

I have been especially concerned during the last few months with the propaganda in collective bargaining negotiations throughout the country for including in union contracts a given number of days of sick leave with pay. All realize that over a period a man or his family will be sick and that he cannot work, year in and year out, 100 per cent of the operating time. The wage rates have been, and should continue to be, based on a reasonable amount of sick absenteeism If they are not high enough they should be increased. But just as soon as more than a reasonable amount of time off for sickness is allowed it is solely an indirect way of obtaining a higher rate of pay and a way which will have the direct result of increasing absenteeism and, therefore, higher operating costs. The Welfare and Retirement Fund in the bituminous coal contract created by the employers paying 5 cents per ton is just an indirect way of paying a higher hourly wage rate. Last winter when the Union Committee in our Southeast Missouri operations asked for fifteen days' sick leave with pay, I thought that it would be of interest to find out just how much time was lost through sickness. For the last six and a half years we have kept a fairly accurate record of our absenteeism, which covers absences of one or more days I would emphasize that our records are based on the employees' statements to us, and it is therefore quite probable that during the hunting and fishing seasons the absentee excuse of a cold may have been somewhat exaggerated. In any event, our sickness figures are therefore more apt to be high than low. In table 1 the detailed figures are available for any one who is interested, and in table 2 the summary figures.

TABLE 2—*Percentage of Shifts Not Worked*

Group	Reasons for Absence	1940	1941	1942	1943	1944	1945	6 Mo. 1946
1	Industrial injury.	0.15	0.15	0.16	0.22	0.32	0.43	0.44
2	Sickness	1.26	1.31	1.04	1.26	2.09	1.98	1.50
3	Personal reasons, including ill defined and unknown causes, illness or death in family. .	0.87	0.85	1.73	2.30	2.97	3.51	2.93
	Total .	2.28	2.31	2.93	3.78	5.38	5.92	4.87

Under the workmen's compensation laws employees are compensated for time lost through industrial injury, so we can eliminate this subdivision from consideration in a sickness calculation. As I do not think that an employee should be paid for time lost because of personal reasons or for illness or death in his family, we can also eliminate the third group. In the circumstances, we are interested in group 2, which shows the time lost through sickness The average for the six and a half year period is slightly less than 1.5 per cent; the time actually lost, on the basis of the employees' own statements to us, is therefore slightly less than five days a year on a six day week and less than four days on a five day week. It therefore appeared to me that the union committee was "negotiating" when fifteen days' sick leave was asked. I am confident that if sick leave with pay had been given the time lost through sickness or alleged sickness would be greater than 1.5 per cent of the shifts worked and the cost of our mining operations even higher.

In further connection with these comparative figures, some one may be interested as to why the time lost from industrial injury has risen from 0.15 per cent in 1940 to 0.44 per cent and the so-called personal reasons from 0.87 per cent to 3.51 per cent in 1945 and back to 2.93 for the first six months in 1946 We felt that accidents would unfortunately probably increase when the five day a week prewar basis was increased to six, when the younger men left for military service and their places were filled with older and more unskilled men, and when through unionization the control of management was lessened through grievance committees' procedure, and so on, as commenced in 1943. The increase in personal reasons is probably because on a six day basis a man was required to take time for family necessities, he became tired under wartime restrictions, and also because with his greatly increased weekly earnings he had sufficient money for his needs without working the full six days. The decrease in 1946 is possibly because with the return to a five day week in May the men have less take home pay even though wage rates were increased to the government pattern of 18.5 cents an hour.

TABLE 3—*Comparison of Claims Paid, Cost and the Like Between Southeast Missouri Mutual Aid Association and a Representative Insurance Company*

St. Joseph Lead Company, Southeast Missouri Division

Number of employees for mutual aid coverage, June 1, 1944:

Eligible to membership	2,674
Actual membership	2,694
Average (weighted) weekly benefit	$ 12.33
Average annual contribution	6.00
Average five year annual contributions	14,899.29
Average five year annual claims	12,131.14*

* As the only cost for services of the officers and the investigating committee is the waiving of their $6 annual contribution, there is no overhead expense. The company deducts the 50 cents per month on authorization of the employee and makes no charge for such service.

The difference between claims and contributions is retained for future claims or emergencies

Therefore the cost is approximately:

Pay in claims ..	$6.00 × 81.4 per cent	=	$4.88 per year
Overhead	.. ..		. per year
Total cost	....		$4.88 per year

Insurance Company

The following figures were submitted as being representative companies, which were somewhat similar to Southeast Missouri, as to number of employees.

Co	Date of Issue	Number Lives	Return in Last Year: Claims per Cent	Return in Last Year: Dividends, per Cent	Return in Last Year: Total, per Cent	Cumulative Return Since Issue: Claims, per Cent	Cumulative Return Since Issue: Dividends, per Cent	Cumulative Return Since Issue: Total, per Cent
1	9/ 1/36	3,357	91.25	0	91.25	72.87	9.35	82.22
2	9/20/40	2,268	88.02	0	88.02	69.96	15.95	85.91
3	9/28/40	2,765	79.50	0	79.50	77.38	2.18	79.56
4	7/ 1/36	3,109	78.67	0.61	79.28	55.40	23.22	78.62
5	12/31/29	2,486	74.86	7.89	82.75	52.51	17.56	70.07
6	11/23/42	2,197	79.20	0	29.20	104.21	0	104.21
7	4/ 5/25	3,863	127.07	0	127.07	64.56	24.72	89.28
8	12/31/27	4,070	84.22	0	84.22	62.79	24.89	87.68
9	5/ 6/40	2,303	70.08	10.18	80.26	56.57	24.94	81.51
10	4/19/26	5,633	91.65	0	91.65	56.30	26.29	82.59

In order to obtain representative weighted average figures, companies numbered 4, 5 and 6 have been eliminated as being above or below the other group figures:

	Per Cent
Average amount paid in claims	65.46
Average amount paid in dividends.	19.02
Insurance Company's handling expense .	15.52
Total premium	100.00

The insurance company offered an estimated annual gross premium of $13.80 for a weekly benefit of $11.80 for any thirteen weeks' period. The premium would be around $14.42 instead of $13.80 for a weekly benefit of $12.33 instead of $11.80 Therefore the approximate cost, after dividends, would be:

Pay in claims	$14.42 × 65.46 per cent	=	$ 9.44 per year
Retain for overhead . ..	14.42 × 15.52 per cent	=	2.24 per year
Total cost	. .. .		$11.68 per year

HEALTH AND HOSPITAL COVERAGE

Another matter that we hear discussed, and one which is becoming a factor in collective bargaining, is the taking out of health and hospital coverage. At the outset let us realize that if the employer pays all or a portion of the cost it is solely an indirect wage and salary increase. In my opinion we should bargain collectively on wages and salaries but not confuse the issue by bargaining on health matters. However, when the question came up at one of our divisions, I said that I would find out what the estimated cost would be if the coverage were taken out with an insurance company instead of the risk being carried by our men themselves, as they have been doing at some of our units for over twenty-five years. The comparison showed (table 3) that the insurance company would pay in claims $14.42 × 65.46 per cent, or $9.44 a year. Return for overhead $14.42 × 15.52 per cent, or $2.24 a year. Total cost, $11.68. Based on our detailed figures, the average amount paid out in claims was 81.4 per cent of the contributions. Therefore the annual cost for sickness coverage per employee was approximately $6 × 81.4 per cent, or $4.88 a year, in comparison with around $11.68 if the coverage was carried by the insurance company.

I feel that the insurance company's payment for claims is about 100 per cent higher than our men's cost ($9.44 in comparison with $4.88) because, since they could increase the net premiums by paying smaller dividends in the event of a poor experience record, they would be more liberal in considering a sickness claim than our men would be. Then, too, our men would be more "liberal" in making claims against an insurance company than against their fellow workmen. In my conversations with the insurance company representatives they make the rather unique statement that the cost was not $11.68 but only $2.24, which was their overhead, as our employees would receive the $9.44, which was better than the $4.88 when they carried all the risk themselves. For obvious reasons, this argument did not appeal to me.

I feel that sickness and hospital coverage can be carried cheaper by the men themselves or by their union than by an insurance company. If, however, they do not wish to assume the risk and desire a policy, they should arrange for it themselves and they should pay the entire cost. If the employer pays any portion, then men, being only human, will take advantage of the policy by "liberalizing" their claims.

CONCLUSION

The sooner labor and management confine negotiations to developing a suitable wage and salary rate structure, stop negotiating on matters that involve payment for time not worked, such as sick leave with pay, payment for liberalized sickness and hospital claims, the sooner our government stops paying subsidies that encourage inefficiency, as is now being done in the mining industry, and stops paying bonuses for not growing products and so on, the better off America and the world will be. The only way in which all can benefit is through increased production and the resultant higher standard of living through having more goods at lower cost. Unfortunately many persons and organizations in the United States are today thinking and conducting their operations on the selfish basis of "he is getting his, so I had better get mine." We should, one and all, think at times Is it for the best interests of our community and our country? and when it is then act constructively!

NEW HORIZONS IN INDUSTRIAL HEALTH AND WELFARE

LABOR AND MANAGEMENT AT THE CONFERENCE TABLE

BORIS STERN
Chief, Industrial Relations Branch, Bureau of Labor Statistics, U. S. Department of Labor
Washington, D. C.

As a fact-finding agency the Bureau of Labor Statistics of the Department of Labor does not initiate or advocate any peculiar or special plans for health or welfare provisions in collective bargaining agreements; nor do we advocate any plans in the other major field of industrial relations, such as wages and hours, seniority problems, problems of vacations with pay and a number of other things which come up for discussion at the labor management conference table. Our job is to keep in close touch with the entire development in the field of industrial relations so that when labor and management get together and ask the Department of Labor to tell them what has been the recent trend, say, in the case of health and welfare development or the case of incentive pay, we ought to be able to provide them with that information. We are also called on by the Congress of the United States to provide that information, and we feel that we have an obligation to the public at large; hence we often also publish that type of information.

Our sources are twofold. First, we maintain in Washington a substantial file of currently active collective bargaining agreements. At present we have about fifteen to sixteen thousand of such agreements on file, and they represent from one fourth to one third of the total number that are in existence in the United States. Precisely how many there are we don't know, because we get our agreements by the process of voluntary submission. We write to the unions or to the employers or to both and ask them to send us copies. If they think that we are reliable and they can trust us, they send us a copy. If, for one reason or another, they do not like us, they throw our letters in the wastepaper basket. Nevertheless we do have a substantial number of collective bargaining agreements which we use as a basis for the facts and the information needed by labor and management in collective bargaining.

When a new problem arises for which we do not have sufficient information but which is of importance to labor and to management, we send out field agents to study the problem on the spot, to find out how a particular program is being put into effect in the plant and how it affects relations between labor and management.

Now, what do we know about health and welfare programs? We know that the present method of establishing such programs through collective bargaining is an innovation and a product of the war. In 1942, when we made an analysis of union agreements for the War Labor Board, we found so few programs of that kind in operation that we did not even mention them in our report. Three years later, in 1945, we found that such a substantial number of health and welfare plans had been put into effect through collective bargaining that we deemed it necessary to publish a special report, which is number 841 of the Bureau of Labor Statistics and is entitled "Health Benefit Programs Established Through Collective Bargaining."

Last spring when the mine workers struck, primarily on the issue of whether or not they were to get a health and welfare fund, the demand for that report was such that our supply of available copies was exhausted within a few weeks. At present we are reprinting that bulletin, and to any one who is interested I shall be glad to send copies on request.

At the time when we published the report we estimated that 600,000 workers were covered by provisions in collective bargaining agreements which provide for some kind of accident or sickness insurance or life insurance, paid for either entirely by the employer or partly by the employer and partly by the union.

At present we estimate that more than a million and a quarter wage earners are covered by collective bargaining agreements which have provisions of that kind. The principal increase since last year, of course, has been in the mining industry with approximately 450,000 United Mine Workers members in the bituminous coal and anthracite mining.

Among the important industries which have special health and welfare clauses in agreements with unions are Men's Clothing, with approximately 275,000 workers; Ladies' Garments, with approximately 200,000; Textiles (all kinds), 125,000; Hats and Millinery, 20,000; Laundry, Cleaning and Dyeing, 30,000. Other industries with health and welfare programs established by collective bargaining for which we do not have precise information as to the number of workers covered are Streets and Railways, the Machinery Industry (particularly electrical machinery), Retail and Wholesale Trade, Fur and Leather, Furniture, Building Trades and Office Workers. Most of the A. F. L. and C. I. O. unions are now interested in programs of that kind.

While the establishment of health and welfare provisions through collective bargaining is thus a comparatively new phenomenon in industrial relations, there is nothing new in the concern of unions and employers with problems affecting the health and welfare of workers. In fact, most of the older unions have for some time had plans by which the union supplied such aid to their members. Many of these unions started as fraternal organizations and their objective was not only to raise wages and improve working conditions but also to supply sickness, unemployment, old age and mortuary aid to the members or their widows. In the course of time, and especially within the last decade or so, unions became aware of the fact that they were not properly equipped to do an effective job in this field. I quote from a pamphlet recently published by the A. F. of L.: "Unions have sponsored their own benefit plans for decades. Often actuarially unsound and overambitious in scope, many of these plans collapsed. At present only eighteen American Federation of Labor Internationals pay health benefits, and the amount is often pitifully small." [1]

Employers too have for some time been concerned with the welfare of their employees—some for humanitarian reasons, because they felt that they were responsible for those who worked in their employ; others, on the other hand, inaugurated welfare programs for their employees primarily to keep them from joining labor organizations. Some of these programs are still in operation, here and there, but not to a degree comparable with the health and welfare plans recently established through collective bargaining.

One who examines those plans, one after the other, will be amazed at the large variety in terms of what they provide for, such as life insurance, sickness benefits, accident benefits, hospitalization and the like. There is also a large variation in the way the plans are put into effect and as to how much money is being contributed to keep them going. There is a large variation as to who administers the program. We regard these variations as extremely worth while because we hope that in the course of time and by the process of experimentation those plans which are not workable and those plans which have been built on unsound ground will disappear and give way to one or several plans which may prove most effective in a particular industry.

There is more involved in the present trend than merely health and welfare programs. Only last week I had an opportunity to examine two new contracts. One was between the Brotherhood of Electrical Workers of the A. F. of L. and the Electrical Contractors' industry. They now have a provision for retirement benefits to the 100,000 electrical workers employed in that industry paid for partly by the union and partly by a payroll tax on the employers. There we have an attempt to take care of the older workers, who, when they reach the age of 65, are no longer in a position to compete with the younger men.

Another agreement, that of the International Ladies' Garment Workers in Philadelphia, provides for payments by the employers to a fund out of which the workers will receive what they call "job security" benefits. The clothing industry is highly seasonal and, time and again, workers find themselves out of a job. In setting up the fund, management and the union inserted another clause which states that it is the objective of labor and of management in that industry to see to it that the workers who now are employed sometimes only eight months or less in the course of the year are to be protected through employment or through benefit payments so that they can live decently throughout the 365 days of each year. In this one sees the beginning of what is now known as the guaranteed annual wage or the guaranteed annual employment.

We in the Department of Labor therefore feel that the new trend of labor and management getting together at the conference table to agree on what is to be done to improve the health and the welfare of the workers constitutes a step in the right direction. Out of the large variety of programs and welfare plans included in collective bargaining agreements there is bound to evolve one or several plans which will prove the most adapted to the needs of the workers concerned and at the same time not too costly for industry and the consumers to bear the burden. Labor has tried to develop a program of its own but has not been entirely successful; management too has tried to protect the health and welfare of its employees through programs initiated entirely by management, but these also have not been successful. It is only when labor and management join forces and cooperatively, with or without the aid of the government, tackle the problem that we can expect real accomplishments.

---

[1] Health Benefit Plans by Collective Bargaining, published by American Federation of Labor May 25, 1946.

ABSTRACT OF DISCUSSION

ON PAPERS OF BOONE, FLETCHER AND STERN

Mr. Boris Stern, Washington, D. C.: My remarks about collective bargaining dealt with what exists in the country and dealt with collective bargaining agreements that we have in the files of the Department of Labor and which we have analyzed. I did not state that certain things should be included in collective bargaining agreements or finally on the problem of whether or not a fund allocated for sickness benefits or for health benefits or for old age benefits is the same thing as an increase in the wages and, as Mr. Fletcher indicated, should be given in the form of wages. I have a feeling that the average worker has not yet been educated sufficiently to be able to invest his wages in that kind of insurance. Therefore, if it is the same thing—if the money is to be expended and we merely have a choice whether it is to be given to the individual worker in the form of a wage increase or whether it is to be given to an insurance company in the form of a future protection of the worker, his children and his family, I—and this is not the position of the Department of Labor, as I am expressing my feeling in the matter—feel that the money invested in the protection in insurance is a much better investment than an increase in the wages or salary structure.

Rear Admiral Joel T. Boone (MC), U.S.N.: I want to make it clear that our group is a fact finding group. We have nothing to do with other groups. In other words, we are making a diagnosis and a prescription; whether it will be taken to a drug store or interpreted by a Christian scientist, I wouldn't know. But we are absolutely impartial. We have no ax to grind, and we have no preconceived ideas. We are naval officers assigned to a job, assigned to a ship at a foreign station. When the job is completed we shall make our report. We shall salute and return to our stations. Now I should like to say, in explanation of the 5 cents a ton regarding the fund for retirement and welfare, that that is a tax on the ton, but the Wage Stabilization Board granted an increase to the operators of the coal. I have often wondered what the definition of "welfare" is. I should be very happy if it is defined and the limitations given to me as to its application.

Chairman Sawyer: Ladies and gentlemen, have we a few questions?

Question: I should like to have Admiral Boone repeat where the money comes from in the two funds and who administers the two funds.

Admiral Boone: The money for the retirement and welfare fund comes from the 5 cents royalty on a ton of coal. The trusteeship is set up for that and it is composed of a member appointed by the union, one by the management, or the United States government, and they select the third member. The second fund is the medical care and hospital fund, and the money for that comes from voluntary pay envelop deductions of the miners and it goes to the trusteeship appointed by the mine workers. The first fund has been accumulating since the 15th of August, and it is being held in escrow in the custody of the paymaster general of the Navy in a New York bank. No trustees have been appointed to date. The government has the mines under operation and for the time being it has been agreed to accumulate the fund and not to appoint the trustees. As to the second fund, Mr. Lewis promised, at my request at the beginning of the survey, that nothing would be done about it until the survey was completed. In other words, the operators were ready to pull out of their medical care and hospital groups, feeling that it was in Mr. Lewis's hands now. There is a fine medical service and hospital program being carried out, and the miners and their families would be left desperate without it. So that until the survey is completed, no action can be taken by that fund. The two funds are to be correlated under the trusteeships.

Question: Is this bituminous agreement going to set standards for the future in other industries?

Mr. Stein: I cannot answer the question about the future. The trend is in the direction of labor and management getting together and by agreement setting up some kind of program which will on the one hand satisfy the needs of the workers and on the other hand be not so costly so that industry could afford to pay it. Whether it will take the form of the fund that has been established for the miners it is hard to say; whether it will be the form of the fund being accumulated by the Garment Workers it is hard to say. Nobody can tell. It may be that half a dozen of those programs will develop in the course of time.

BLAST INJURY

CAPTAIN R. HAROLD DRAEGER (MC), U.S.N.
JOSEPH S. BARR, M.D.
and
W. W. SAGER, M.D.
Bethesda, Md.

The detonation of a high explosive in the vicinity of the human body may result in various injuries, depending on which of the three states of matter, gas, liquid or solid, effectively transmits the force of the explosion.

The effects of an explosion in air and water have been described in medical literature in considerable detail.[1] Recently a new clinical entity, solid blast,[2] has been described, in which the force of an explosion is harmfully transmitted to the human body through solid structure.

This paper is concerned with a comparative study of the three types of blast injury—air blast, water blast and solid blast. The physical forces, mechanism, pathology, clinical features, prevention and treatment of such injuries are briefly considered.

NOMENCLATURE

Blast injury is an acceptable generic term for the various harmful effects of an explosion on the human body. Air blast, water blast and solid blast may conveniently designate the three types of blast injury. The word blast relates to the causative explosion; the terms air, water and solid denote the material medium which harmfully transmits the explosive force. Each of these three types produces various effects, which, broadly considered, include all the injuries which may be inflicted by the detonation of a high explosive.

The medical literature contains a variety of terms which have been applied to blast injuries. Wind of shot,[3] reflex paralysis,[4] bomb blast, shell shock, concussion and other terms have been used to designate the effects of an explosion in air. Underwater concussion, submarine blast and immersion blast have been used to indicate the effects of underwater explosion on immersed persons. Likewise the names deck slap, deck

heave and destroyer heel have been used to designate the effects of the acceleration of a deck structure caused by an explosion in the proximity of a ship. This confused terminology is simply resolved by the use of the terms air blast, water blast and solid blast.

AIR BLAST

The detonation of a high explosive in air results initially in an extremely rapid outward movement at supersonic speeds of hot gases generated by the chemical reaction of the explosive. An air compression wave is thus produced which travels outward at sonic speed (about 1,100 feet per second). Such an air pressure wave subjects everything in its path first to an outward thrust as the wave front strikes the object, then to compression as it is enveloped by the wave, and finally to a minor wave of negative pressure. The effects of an air pressure wave are apt to be erratic, owing to the alteration of pressure by reflection resulting in cancellation by interference or augmentation by reinforcement.

An explosion is also associated with the liberation of a large amount of energy in the form of heat. This is dissipated in part as radiant energy (light and heat) and largely by the outward movement of hot gases. The thermal effect, although of only a few milliseconds duration, may cause serious "flash burns," particularly of the exposed portions of the body.

The energy of an explosion is also transmitted to neighboring objects, moving them outward with great velocity. From the standpoint of trauma to the human body, secondary injuries from flying débris and metal fragments and from the person being thrown against fixed objects are most important.

It is unnecessary in this paper to discuss wounds, cuts, contusions and thermal injuries such as flash burns. Such injuries are common, easily recognized and clinically well understood.

The pressure wave of an explosion in air produces certain interesting and important primary effects on the human body. Chief among these is pulmonary blast injury. The severity of pulmonary injury more nearly determines the fate of the individual than any other primary injury caused by air blast. Damage to the lungs interferes with respiration and produces shock.

The respiratory symptoms and signs are embarrassment of breathing, cyanosis, pallor, restlessness and frank hemoptysis or blood streaking of the sputum.[5] Pain in the chest is a constant symptom and is of two types. There may be pain felt centrally, deep in the chest, due to mediastinal hemorrhage or emphysema. There is also in the majority of the cases lateral pain due to pleural and chest wall injury, made worse by respiratory movements.[6] Respirations may be either rapid or slow. Barrow and Rhoades described the respiration of their patients as slow, shallow and sighing, except when severe pain was present, and then the patients gasped for breath. Cyanosis, the result of deficient aeration, occurred in many instances within an hour or more after the injury. Cough has been noted and may last several days.[7] Burbank and Forsee[8] describe a ballooning of the lower part of the chest as the most characteristic finding on physical examination. In uncomplicated cases the resonance on percussion is normal. Breath sounds are weak, and coarse bronchial rales may be heard on auscultation.[9]

At autopsy in fatal cases the findings vary in severity.[10] The lung may contain various amounts of extravasated blood. Lockwood[11] in describing the injuries to the lungs in World War I stated that rupture of the visceral pleura or a complete collapse of the lungs occurred in severe cases. The alveoli may contain blood from a tear in the interalveolar septum or from lacerations along the lines of the ribs. Red hepatization may occur.[12] As would be expected on x-ray examination, various areas of increased density are visible.[13] The bases, rather than the apexes, are the areas where x-ray changes are usually seen.

Abdominal pain, which is characteristic of water blast, is infrequent in air blast, but sometimes it and rigidity are predominant features. In an occasional case these symptoms are so prominent that a laparotomy appears to be imperative, but as a rule on exploration only punctate subserosal hemorrhages are found.[14] The abdominal pain in some instances may be referred from the chest, or rarely it may result from abdominal visceral injury.[15]

A striking clinical feature is the effect of air blast on the central nervous system. The prominence and ease of recognition of the symptoms attributable to lesions of the central nervous system caused overemphasis of this feature during the first world war. Since that time a clearer conception of the nature of these injuries and their relationship to the symptoms found in cases of air blast has been attained.[16]

Those whose symptoms are purely psychogenic and have no organic basis are apprehensive, lose weight, eat poorly, do not sleep well and have terrifying dreams. The symptoms of those suffering from organic brain damage are lethargy, slow cerebration and lack of interest. They are not apprehensive, sleep more than normal rather than less, usually gain weight and have a normal appetite.[17] The degree of lethargy, according to O'Reilly and Gloyne, is indicative of the severity of the injury.[18] It is thought to be the result of petechial hemorrhages in the central nervous system.

Abbott, Due and Nosik[19] called attention to cases of subdural hematoma and effusion in which there was a history of severe concussion and loss of consciousness for periods varying from a few minutes to several days. There were persistent headaches, loss of memory and irritability. Rarely were positive neurologic signs present, and those that were present were not pronounced. The most common findings were a slight facial palsy, a transient hemiparesis and occasionally a transient change in reflexes. Without careful study these patients would be discharged from the military service as chronic invalids with a diagnosis of a functional disorder.

Zuckerman reported in 1941 that, in experimental animals exposed to high air blast pressures, pial and ventricular hemorrhages occurred. Hemorrhages, especially in the thoracic cord, were found about the spinal roots.[20] The work of Denny-Brown and Russell[21] on cerebral concussion is of interest in that they called attention to concussion produced by the acceleration of the head.

Injury to the ears has been described by many authors, and in some cases ear lesions are of diagnostic significance.[22] Tinnitus, deafness and pain referred to the ears were almost universal immediately after the explosion. The most severe immediate deafness was associated with hemotympanum rather than with perforation. In patients with actual hemorrhage into the ear drum, usually in the region of the umbo and the handle of the malleolus, there was almost complete deafness. Recovery of this group was rapid, with but little impairment of hearing after two weeks. Perforation of the ear drums, varying in size from a complete loss of the entire membrane and ossicles to small slits, occurs frequently in air blast. There is no apparent relationship between loss of hearing and the size of the perforation.

Ocular symptoms and signs may occur; a sensation of grit in the eyes, photophobia, blepharitis and lacrimation are the most usual. Three cases of subconjunctival hemorrhage and 1 of clouding of the corneal epithelium occurred in Barrows and Rhoads's[7] cases. Blindness as a result of air blast is rare.

Shock is present in all cases of air blast injury. Electrocardiographic study of a series of cases showed a flattened QRS complex and a normal sinus rhythm.[7] No arrhythmia or fibrillation was found. A subnormal temperature on admission to the hospital was followed by a slight rise four to twelve hours later.[7] Hooker[23] experimentally produced in animals a sudden drop in arterial pressure to approximately one half of normal, a condition he describes as "primary shock." His animals showed pulmonary damage at autopsy. Pugh[17] called attention to the large vascular bed found in the lungs, which, when injured, afforded a sufficient etiologic factor for the production of shock. It must also be remembered that usually the entire body is exposed to the effect of the blast; many undiscovered lesions may aid in the production of shock. Abbott, Due and Nosik[19] state that examination of the fatal cases at autopsy reveals multiple hemorrhages throughout the body. As would be expected, lesions of other organs have been reported, but these occur in isolated instances.[20]

Treatment of air blast is the treatment of shock and of such other lesions as may be present. Lockwood[11] advised that these cases should be sought among those lying about close to the site of an exploded shell or bomb. Oxygen therapy is generally accepted as being of great value and should be started at the earliest possible time. Bed rest and a minimum of transportation and handling are of utmost importance. Plasma and other intravenous fluids should be given carefully, owing to the danger of increasing the amount of pulmonary hemorrhage.

WATER BLAST

The detonation of a high explosive in water also results initially in an extremely rapid outward movement of hot gases, generated by the chemical reaction of the explosive. A water pressure wave is thus produced which travels outward at sonic speed (about 4,800 feet per second). Immersed persons traversed by such a pressure wave and subjected to forces of compression greater than 500 pounds per square inch are apt to sustain fatal injuries from rupture of the intestine or of pulmonary vessels.[24] Corey[25] states that an underwater blast pressure of over 250 pounds per square inch will result in intestinal perforations and that even lower pressures must be looked on as dangerous.

Since the human body has a density approximately equal to that of water, it is traversed by the water pressure wave and only the air-containing portions of the body are subjected to sudden compression and reexpansion. This causes rupture of tissues adjacent to the contained air, chiefly the lungs and intestine. The head usually escapes damage, as it is held out of water.

Secondary injuries in water blast are much less frequent than in air blast, owing to the restraining effect of water on metal fragments and wreckage. However, because of its greater density, water will harmfully transmit the primary pressure wave for a much greater distance than air. Flash burn effects are inconsequential in water blast.

Water blast was recognized in World War I, but it has been only in the recent war that a careful study of this phenomenon has been made. Mathew[26] of the Royal Navy described 10 cases in 1917. In 1940 Atkins[27] described 3 cases which occurred during the evacuation of Dunkirk. Breden, d'Abreu and King[28] reported cases resulting from the explosion of torpedo and depth charges. Greaves and Draeger[15] and Friedell and Ecklund[29] have published experimental work. Many other studies of value have been made. At present our knowledge of this form of blast injury is equal to that of air blast.

The sensation of having received a "quick punch" in the abdomen, or a feeling of compression of the chest and abdomen, is complained of by survivors. In some cases there is only mild discomfort after this initial sensation, in other instances the abdominal pain within thirty minutes becomes very severe. Later, frequent bloody stools may be passed. If there has been a perforation of the bowel, evidence of peritonitis will develop and a paralytic ileus may manifest itself.

The abdomen may become rigid as a result of perforation of the intestine, from subserous hemorrhage of the intestine or from referred pain from the chest when there is associated chest injury. Shock is present in all cases, as described in air blast.

The abdominal pathologic changes consist largely of lesions of the gastrointestinal tract.[30] Hemorrhagic lesions, varying in size and shape, may occur in every part of the tract from the stomach to the rectum. Considerable edema of the bowel may be present. Perforations may be found at points where the bowel contains perceptible amounts of gas.[31]

Injury to the chest is less frequent than in air blast; when it does occur, the symptoms and pathologic changes are similar to those of air blast. The cranium is least frequently injured because it is not often immersed at the time of the explosion. When injury is suffered, the symptoms and pathologic changes are similar to those of air blast.

The patients should be carefully watched, treated for shock and kept on bed rest. Handling and transportation should be avoided as much as possible. Sufficient fluids, including plasma and whole blood, to maintain fluid and electrolytic balance should be given. A Miller-Abbott tube should be used in cases of paralytic ileus. Sufficient sedation should be given to relieve pain and apprehension. Considerable difficulty may be experienced in determining the necessity for surgery, which is always indicated in perforation of the intestine. Decision in this, however, must of necessity depend on the judgment of the individual surgeon.

SOLID BLAST

The detonation of a high explosive in the proximity of a semirigid body, such as a ship or a tank, results in the transmission of energy through the solid structure as a flexion wave, resulting in a sudden acceleration of deck and bulkhead surfaces.

These sudden accelerations are capable of causing serious injuries to personnel. Since this type of injury is caused by a sudden acceleration, the damage is greatest at the point of contact. Injuries of the lower extremities, particularly the ankles, are therefore most common. Secondary injury due to the victim being thrown against the overhead or, in the case of ships, overboard is also frequent.

The pathologic changes in the human body produced by solid blast bear little resemblance to those of air or water blast. The primary injury is predominantly skeletal and vascular, chiefly affecting the lower extremities. We[2] have presented elsewhere a detailed study of the injuries which occurred in 50 cases in which the effects of solid blast were studied.

Injuries involving the ankle and tarsal bones are most common and characteristic. These injuries are usually compound comminuted fractures involving the os calcis, astragalus and the distal tibia and fibula. In 36 per cent of our cases such injuries were suffered. Less frequent injuries are fractures of both bones of the leg (18 per cent). About one half of these are compound fractures.

Fractures of the tibial condyles, involving the knee joint, occur in about one fourth of the cases and are rarely, if ever, compound.

Dislocation of the knee, with or without associated fracture, is a frequent and extremely serious injury (20 per cent of the cases). Irreparable vascular damage necessitating amputation occurs in the majority of the dislocations. Peroneal nerve damage, resulting in foot drop, is associated with dislocation of the knee in a few instances.

Fractures of the femoral condyles and of the shaft of the femur, hip and pelvis are rarely seen in solid blast injury. On the other hand, fractures of the spine occur quite frequently (18 per cent of the cases); in about half of them there is associated cord or cauda equina damage resulting in partial or complete paraplegia. Fractures of the skull, face and upper extremities occur infrequently.

Cartilaginous aseptic necrosis of the ankle, knee and hip occurs frequently as a result of trauma to the articular cartilage of these joints and may be present without fracture or infection. This cartilaginous damage results in partial or complete loss of motion of the involved joints in many instances.

Soft tissue wounds associated with compound fractures occur in about 30 per cent of the cases and are usually caused by penetration of bone fragments from within outward. In addition to these wounds, severe ecchymosis and contusion about the ankles is frequently observed.

Vascular injury associated with dislocation and fracture of the knee occurs often in the form of rupture or thrombosis of the popliteal vessels. This is a serious injury, and the ensuing gangrene often necessitates amputation. Damage to the contents of the thorax and abdomen has not been seen as the result of solid blast.

Cerebral concussion as evidenced by transitory loss of consciousness occurs in about two thirds of the cases. Paraplegia of some degree is present in about half of the cases of fracture of the spine.

Exact figures on mortality and morbidity rates among persons subjected to solid blast are not available, but examination of the casualty figures reveals that among ship's personnel the probability of being killed or injured aboard a small ship or a craft subjected to mine or torpedo explosion appears to be approximately one third of the crew killed, one third injured and one third uninjured. Many victims close to the explosion are killed immediately or die within a very short time, presumably as the result of cerebral injury or as a result of drowning while unconscious. Those who survive the immediate effects of the blast may succumb later from shock or paraplegia. One patient on whom postmortem findings are available died seven days after injury. The chief findings were hypostatic congestion of both lungs, cloudy swelling of both kidneys, free fluid in the pericardial and pleural cavities, multiple fractures, a compound dislocation of the right knee and gangrene of both lower extremities. The cause of death was recorded as shock resulting in renal failure and uremia.

Most cases of solid blast injury have occurred as the result of maritime disasters in which ships were blown up or severely damaged. "On the spot" clinical recorded observation of these patients is scarce, as skilled medical care and adequate equipment are rarely available immediately. Surviving victims exhibit a variety of clinical signs and symptoms. Approximately one half or more are unconscious or dazed as the result of cerebral concussion, and most of the victims exhibit classic signs of shock. Almost all the severely injured have bilateral fractures of the lower extremities, and about half of them are compound. Swelling of the soft tissue of the ankles and lower part of the legs occurs rapidly and develops to such a degree that it prevents effective manipulative reduction of the fractures. Patients who have fractures and dislocations of the knees almost inevitably develop gangrene of the feet and lower part of the legs, with the usual clinical findings of cold, livid skin and absence of pulsation of the vessels.

[30] Yaguda, A.: Pathology of Immersion Blast Injury, U. S. Nav. M. Bull. **44**: 232-240 (Feb.) 1945. Clark, S. L., and Ward, J. W.: The Effects of Rapid Compression Waves on Animals Submerged in Water, Surg., Gynec. & Obst. **77**: 403-412 (Oct.) 1943.

[31] McMullin, J. J. A.: Foreword to Symposium on Immersion Blast, U. S. Nav. M. Bull. **41**: 1-31 (Jan.) 1943.

Personnel who happen to be sitting down when subjected to solid blast have the shock wave transmitted directly through the pelvis and are most likely to receive fractures of the spine. Such spinal fractures are practically all in the dorsolumbar area; in about half the cases there is associated paraplegia. Personnel standing at the time of the explosion may be tossed against the overhead or fall back against the deck after being thrown into the air with such force that secondary fractures of the spine are produced.

As most solid blast injuries are the result of a major maritime disaster in which a ship is blown up or severely damaged, the patients receive a minimum of medical care during the first hours after injury. Attention is directed primarily to rescue and resuscitation from immersion, treatment of shock, simple splinting of fractures, dressing of wounds and transportation to a place where adequate medical care is available. The surgeon's first duty is to assess the general condition of the patient and to combat shock, if it is present, by administration of fluids, transfusion, complete bed rest and sedatives. The next is a complete physical examination, supplemented by the necessary x-rays, in order to determine the exact type and degree of injury. The injuries are almost always multiple, and many of them will be overlooked if the examination is not thorough. The exact treatment depends on many factors, including the type and severity of injury, the condition of the patient, the time elapsed since injury, and the judgment and skill of the surgeon, but certain general principles are applicable:

Soft tissue wounds should receive early attention. If they are not obviously infected, devitalized tissue should be excised and adequate drainage insured by lightly packing the wound. Systemic chemotherapy should be instituted. Primary closure of these wounds is usually not feasible because of the severe trauma to the surrounding soft tissues, although delayed closure may occasionally be possible. Fractures about the ankle and of both bones of the leg, which are often present, are usually severely comminuted, crushed, displaced and accompanied with extreme swelling of the soft tissue. As a result, anatomic reduction is rarely possible. The most successful method of dealing with such fractures appears to be by manipulation and molding of the fragments. Shortening should be reduced and impaction broken up by preliminary traction, preferably by means of a Kirschner wire through the os calcis. After reduction, the leg should be immobilized in a carefully molded plaster cast. The Kirschner wire should be removed within a week or two, as there is little or no tendency for overriding to occur in these comminuted fractures. Open reduction by operative means, and the use of external skeletal fixation by multiple pins, greatly increases the chances of sepsis occurring, and are rarely, if ever, indicated.

When there are fractures and dislocations of the knee joint the displaced bones must be reduced as soon as possible; the circulation of the limb must be carefully watched for impairment. The leg should be slightly elevated and immobilized in a bivalved plaster cast. Procaine lumbar sympathetic block should be used repeatedly in every case of impending gangrene. In spite of these measures, an open flap or guillotine amputation will frequently be necessary because of gangrene.

The great variety of secondary fractures and miscellaneous injuries present no special difficulties and should be managed in the usual fashion.

The rehabilitation of these cases, after the acute phase of convalescence is over, demands a combination of surgical, physical, occupational and psycho-therapy.

Open wounds and draining sinuses from compound fractures are eradicated by carefully planned surgery, if they do not heal spontaneously in a reasonable time. Operative treatment includes eradication of the sinus tract and removal of sequestrums. In a few instances a large bony defect has been packed with dried plasma and penicillin powder (1 Gm. of powdered plasma to 200 units of penicillin). The soft tissues and skin are then closed by plastic procedure or the operative defect is allowed to granulate in.

Physical therapy is necessary in all cases to restore joint function and muscular strength. Weight bearing, even with crutches and properly fitted shoes, is at first very difficult and painful. However, in spite of extremely severe injuries involving the weight bearing joints, many of these patients eventually develop surprisingly good function. Operative intervention should usually be deferred until its necessity has been completely demonstrated by the test of use.

Among the late operative procedures which may be necessary are (*a*) lumbar ganglionectomy to improve the circulation in the lower extremity; (*b*) removal of irregular bone spurs and displaced fragments which lie in the soft tissues of the sole of the foot, lateral incisions for their removal being preferable; (*c*) stabilization of the foot by some type of triple arthrodesis; (*d*) fusion of the ankle or knee joint; (*e*) ligamentous repair of the knee; (*f*) amputation of useless extremities.

PROTECTIVE MEASURES

The protection of the human body against the effects of an explosion depends on preventing a harmful amount of energy from reaching the body. This can be accomplished by a device which breaks the continuity of the medium through which the energy is being transmitted.

The only effective protection against air blast is the interposition of solid material which absorbs or deflects the hot gases, the blast wave and the flying fragments. An air raid shelter or fox hole are examples of this type of protection. Personal protective devices (special clothing and antiflak vests) have been devised for protection against flash burns and flying fragments. Ear defenders will prevent perforation of the ear drums, but there is no practical personal device which is effective in shielding the chest and abdomen from the air pressure wave.

Protection against water blast is readily obtained by interposing a layer of cellular air-containing compressible material between the air containing portion of the body (chest and abdomen) and the surrounding water. A kapok life preserver 1 to 2 inches thick gives protection against many times the lethal wave pressure of 500 pounds per square inch, provided the chest and abdomen are completely covered and the head is out of water. A device of this size is too cumbersome to be practical. However, many lives have been saved through a better understanding of the nature of water blast injury and the observance of certain safety precautions. Wearing a properly fitted life jacket,[32] swimming away from a sinking ship or other source of likely underwater explosion and getting as much of the body out of the water as soon as possible are practical measures.

Protection against solid blast may be accomplished by interposing a deformable collapsible medium between the solid surface and the human body at the point of contact. Antiblast mats and shoes constructed to support normal body weight, but which collapse under increased pressure, will afford a considerable degree of protection.

ABSTRACT OF DISCUSSION

Dr. William F. Holcomb, Oakland, Calif.: The presentation of this paper on blast injury is a distinct contribution to the medical record of the war. The first hand knowledge of these pathologic conditions has been splendidly summarized and a simplified terminology proposed. This valuable record will serve as a summary and an account for the use of future historians. When the term blast injury comes to my mind it is always associated with masses of patients being dirty. Those that are affected with air blasts are dirty and torn from the effects of dirt being driven into the body with explosive force. They are often also covered with fuel oil, which certainly is the most prominent feature of those that are involved in water blasts. The dirty and disheveled appearance of those persons who are in compartments where solid blasts have been produced is most striking. In U. S. Mobile Hospital number 2 most of our time was spent in cleaning up the patient for further transfer. This was probably a valuable occupation, for it kept us busy from producing harm by heroic treatment. The description of the kinds and characters of fractures received from various types of injury is excellent. Fractures of the metatarsal heads were not particularly mentioned but appeared to be rather common in those cases which we received in Hawaii. Why the metatarsal head should be broken just at the base and set up on top of the shaft I cannot say, but a number of cases of that type were seen in which all five metatarsal heads were completely and cleanly broken at their base and were displaced approximately the width of the head. It is difficult to explain why or how so much damage can be done to the ankle, foot and leg, as well as to the knee, without having a fracture of the femur, either in the condyles or on the shaft. I saw only one fracture of the femur, associated with other signs of blast injury, in a fatal case occurring off Balikpapen, Borneo. I believe that the description which the authors have given of the initial difficulties in diagnosis might be augmented. In the sinking of the *Yorktown* and the *Hammann* there were cases in which an air blast from a falling bomb, a solid blast from the ship's explosion and a water blast from the detonation of the depth charges of a sinking destroyer were received. These persons presented problems in diagnosis and treatment which were extremely complicated and were probably often poorly evaluated. One junior medical officer started from the scene of the battle of Midway with 125 men coughing blood from the effects of their water blast, many of them passing blood by rectum and all of them suffering from shock and immersion. The heroic work and self sacrifice of these destroyer medical officers will long be remembered by those who received their treatment or knew of their efforts.

Dr. Stephen Holstein, New York: I had the poor fortune of having the largest accumulation of cases that the Navy had right after D day, and I was interested in exactly this injury. I wondered if anybody had done any investigation on the results of this direct thrust of solid blast. I called the injury "concussive injury sustained aboard light craft." I found that the shafts of the long bones were not involved. The femur was involved not at all in our investigations, the tibia in 1 case. The first point of contact was in the os calcis or the os tragicus, the second in the knee, the third within an inch or an inch and a half of the ankle. By careful questioning it was easy to determine exactly what the injury was before the x-ray film came back. If the patient was solid on the deck and the thrust was a direct thrust, if he was on a destroyer escort—which is a light vessel—and the thrust was directly upward, one could be certain that he had an os calcis fracture and nothing else. If, however, the thrust caused the craft to skip a little along the water, the injury was on the knee. If the thrust was upward and out, the injury was at the ankle about an inch above the articulation with the astragalus. The question I should like to ask is this: With the shoe devised as the result of the experiments, I can readily see how a direct upward thrust of the deck aboard a light or moderately heavy ship can be overcome. Were any experiments conducted on direct lateral or lateral and upward thrusts in the course of the work done?

Dr. Joseph S. Barr, Boston: I had anticipated there would be criticism of the term "solid blast." It does not fall on the ear immediately as something that one recognizes as to its connotation. We went over all the variations of suggested terms and finally fell back on the subterfuge of coining one. If we are going to have such a clinical entity as air blast and as water blast, it is fairly obvious that with the force transmitted through solid material "solid blast" might be an acceptable term. The patient does not have to be standing in order to get a solid blast injury. A number of our patients were sitting. Those patients sustained fracture of the spine. They were the ones who sustained paraplegia. One patient was lying in his bunk at night with his feet against a steel bulkhead, and he sustained fractures of both os calces, so it is not necessary to be either standing or sitting. Though the bed or bunk is quite a satisfactory protective device, it does not prove to be 100 per cent protective. In the 50 cases which we analyzed carefully and which I myself saw, none presented what we felt were primary fractures of the metatarsal heads due to solid blast. One or two had secondary injuries. They had been tossed such distances that on landing they had sustained injury to the metatarsal heads. Perhaps fracture of the metatarsal heads can occur as a result of primary solid blast, but it is probably extremely rare. Fracture of the femur in our experience was the same as that of the two discussers; it rarely occurred as a primary effect of solid blast. As to experiments on lateral thrust, I am not a physicist and am not able to discuss that. This problem is still being worked on in the Navy. We discussed that possibility at great length with physicists of note, and they have felt that lateral accelerating forces could scarcely be imparted to the human body from the ship. If one is standing vertically and there is a lateral thrust, the knee might possibly be strained, but that lateral thrust did not account for the dislocations to the knee that we saw. Probably the individual variations in anatomic strength of various areas may account for the differences in the types of fracture. In one person the os calcis will be fractured, in another the lower end of the tibia will be fractured. Position has something to do with it. Those who happened to be standing with their knees slightly flexed may have sustained dislocations of the knee in one direction, whereas if they were standing with the knees hyperextended they might have sustained a dislocation in another direction. These are hypothetical answers to the question, and we must await further experimental evidence before we are didactic about it.

ACCIDENTS ON THE FARM

H. HERMAN YOUNG, M.D.
and
RALPH K. GHORMLEY, M.D.
Rochester, Minn.

The number of accidents that occur on farms each year and the severity of the resultant injuries have for years been appalling to doctors in agricultural communities, and yet to date comparatively little work has been done to prevent these accidents. In the past the national state and local safety councils have directed all their efforts toward the prevention of traffic and industrial accidents and have turned to the problem of farm safety only recently.

In Minnesota attention was first directed to the problem of farm accidents in 1934. In that year a safety contest was inaugurated in the state 4-H clubs, and safety soon became one of the most popular activities of these clubs. Other agricultural organizations and their leaders became interested, and a section soon was set up in the Minnesota Safety Council to which was assigned the problem of developing an educational program for the farmers of the state. As a result of the efforts expended, the farm safety program in Minnesota has now progressed from the state planning stage to local action. Emphasis is now placed on organized work in the counties and individual townships; the latest innovation is the holding of regional farm safety institutes in various sections of the state. To these meetings come representatives from the local farm bureaus, rural youth organizations and 4-H clubs in the surrounding counties. At these meetings members of the various sections of the Minnesota Safety Council and a doctor who has been called on to treat farm accident cases discuss with these representatives the causes of farm accidents and the means of preventing them. The representatives carry back to their local organizations the information they have received. Each county then plans its own safety program and proceeds with it. One county conducted a survey of farm accidents which revealed the fact that the total loss of time due to accidents in that county during one year amounted to six man years. In another county members of the farm committee of the safety council called on every owner of a corn picker and discussed safety. The result was the complete elimination of mishaps caused by the corn picker in that county that year.

The problem of accidents on the farm is national in scope, although in details it varies with different localities. Tractors are used fairly commonly throughout the country, but other pieces of machinery are employed only in certain sections. All farmers in the corn belt are familiar with the mechanical corn picker but may not be so familiar with the large combines of the wheat country and so forth. Various other sections of our country have their individual differences, but the basic need of all sections is that the farmers learn to use their machinery safely. The National Safety Council now has a section which promotes farm safety in all sections of the country, but the main action on prevention of farm accidents of necessity must be local in nature in order to cope with the varied problems.

Farming is today one of the most hazardous of all occupations. Other industries are compelled by law to provide safety devices for their employees and care and compensation for any one who is injured. Many individual industries have realized the importance of safety for their employees, and they not only conduct safety courses for the operators of various machines but penalize any employee failing to comply with safety requirements. They are constantly on the alert for the causes of accidents in their plants and attempt to remedy them. This is not true of the farmer.

The farmer is generally his own boss or employs only a few men. As a rule he does not carry compensation, hospital or accident insurance. However, he is handling machinery that is as powerful as many other industrial machines and handling this machinery over rough ground in contrast to many industries that can bolt the machine securely to a solid floor. Furthermore the farmer uses his various machines seasonally, whereas the operator of a punch press, for instance, uses the same machine daily and has an opportunity to become familiar with the sources of danger. In order to speed up production, the farmer permits the removal of safety devices from his machines or fails to replace them after repairs are made. He often attempts to relieve a clogged machine while it is still in motion or may use a piece of makeshift apparatus that is entirely unguarded. He uses old timber when safe flooring is necessary, operates buzz saws unprotected, handles unruly livestock, is required to walk on uncertain footing and in countless other ways exposes himself to danger. In doing his tasks he is out in all kinds of weather and must often wear bundlesome clothes that hamper quick movements. These are but a few of the dangers that lurk on the farm. To these must be added the danger of gas gangrene and tetanus, for the farmer's hands and clothes are contaminated with fertilized soil and manure, and any wound may permit the entrance of these organisms into the body, where they produce disastrous results.

* Average of 64 farm accidents per year seen at the Mayo Clinic.

In spite of medical and surgical advances that have been and are being made, the physician cannot help but be impressed with the almost utter hopelessness of many patients who have been injured while at work on a farm. The best cure still lies in prevention of the accidents. The first step in prevention likewise lies in educating the farmer to the facts of how, where, when and why accidents happen on the farm.

Accurate and complete statistics on farm accidents in our country are not available. So that one may know the problem that exists, such statistics must be available; and it is for this reason that the records of the Mayo Clinic were recently reviewed. Since the clinic is situated in a farming community, it was felt that this review might throw some light on the problem.

From the Section on Orthopedic Surgery, Mayo Clinic.

Read before the Section on Orthopedic Surgery at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

STUDY OF 575 FARM ACCIDENTS

In the nine years from 1935 through 1943 there were 575 accidents on the farm which caused the person injured to come to the Mayo Clinic. This makes an average of 64 farm accidents a year which sent patients to this one clinic alone. Several patients were involved in more than 1 accident in the nine years. The majority of these patients came from the surrounding four or five counties, but the total number is not an index of the total farm accidents that occurred in those four or five counties. Many other patients were treated by physicians in their immediate locality and others died before reaching medical care. The total at the clinic may be said to represent with fair accuracy the number of serious accidents that occurred in these counties during that period. Included in the study were all accident cases encountered at the clinic which were due to falls, farm machinery, livestock, injuries in the farm home, buzz saws and so forth. All automobile and highway accident cases were omitted.

Table 2.—*Injuries Sustained in 193 Accidents on the Farm Due to Falls, 1935-1943 Inclusive*

		Injury *				
Type of Fall	Total Accidents	Fracture	Transverse Myelitis	Traumatic Amputations	Perforating Perineal Wounds	Miscellaneous †
Off farm equipment	42	29	4	0	3	12
Miscellaneous types	39	29	0	0	3	14
From haymow	20	15	3	1	3	1
Off buildings	16	18	3	0	0	1
On stairs	16	15	2	0	0	2
Off horses	15	12	0	0	0	3
On ice	11	12	0	0	0	1
Off ladders	12	15	0	0	0	4
Off scaffolds	12	13	3	0	0	0
Out of trees	8	10	1	0	0	0
Total	193	168	16	1	9	38

* Some patients had more than 1 injury.
† Lacerations, dislocations, cut tendons and so forth.

Falls.—Falls led all other causes of accidents in this series and carried a mortality rate of 5 per hundred accidents (table 1). The commonest accident of this type was that in which the patient fell off some piece of farm equipment. In close succession then came miscellaneous falls—falls from haymows, buildings, stairs and horses, on ice and off ladders, scaffolds and out of trees (table 2). The youngest person injured in a fall was 3 years of age and the oldest 84 years. The average age of the patients in this group was 42 years (table 3). The commonest injury sustained was a fracture of one or more bones. Falls caused 168 fractures (table 2). In addition 16 patients, 3 of whom died as a result of their injury, had transverse myelitis, 1 had a traumatic amputation and 9 had perforating wounds of the perineum. Three of the last group died as a result of their injury. The perforating wounds of the perineum are interesting because of the manner in which these accidents happen. Eight of the 9 patients suffering from perforating wounds of the rectum or perineum gave the history of impaling themselves on the handle of a pitchfork as they fell or jumped from a piece of farm machinery or as they slid down a haystack or out of the hayloft. The handle of the fork entered the rectum of 1 patient without causing any external wound; yet at necropsy nine perforating wounds in the bowel and a ruptured liver were found. The remaining patient in this group sustained his injury when he fell from a wagon and became impaled on sharp corn stubble in the field. It is interesting to note that in this entire series no patient was injured with the tines of the pitchfork.

Table 3—*Range of Ages of the Persons Involved in 575 Accidents on the Farm, 1935-1943 Inclusive*

	Age of Patient, Years		
Type of Accident	Youngest	Oldest	Average
Falls	3	84	42
Machinery	2	78	37
Livestock	3	85	46
Burns	7 mos.	83	35
Falling trees	17	71	44
Ax	16	62	29
Unclassified	15	84	42
For whole series	7 mos.	85	39

Farm Machinery—Accidents attributed to farm machinery followed falls in a close second place as the cause of farm accidents in this series; there were 186 such accidents (table 1). Although there were no hospital deaths in this group (table 1), the morbidity rate was extremely high. Exactly a third of the patients in this group suffered from traumatic amputation of a part or the whole of one or more extremities. There were in addition 110 fractures, 2 cases of transverse myelitis and 7 cases of avulsion of the skin of the penis and scrotum. The youngest patient injured by a piece of farm machinery was 2 years old and the oldest was 78. The average age in this group was 37 years (table 3). The tractor caused the largest single group of accidents and was followed closely by the corn picker, corn shredder and buzz saw (table 4). The injury of particular interest in this group is that of avulsion of the skin of the penis and scrotum. It happens usually as the farmer attempts to step across a moving belt or flywheel. The overalls become caught in the belt or wheel and are twisted and torn from the patient's body. As the clothing is torn off, the skin of the penis and scrotum becomes entangled and is stripped away. These accidents produce shock, and considerable surgical care is required for restoration of the parts by skin grafting.

Table 4.—*Injuries Sustained in 186 Accidents on the Farm Due to Machinery, 1935-1943 Inclusive*

		Injury *				
Machine or Method	Total Accidents	Fractures	Transverse Myelitis	Traumatic Amputations	Avulsions of Penis and Scrotum	Miscellaneous †
Tractor	34	33	2	2	0	12

Miscellaneous machines	4	1	0	2	0	2
Total	186	110	2	62	7	71

* Some patients had more than 1 injury
† Lacerations, dislocations, cut tendons and so forth

Livestock.—The third most frequent cause of the accidents in this series was livestock; there were 104 such accidents (table 1). The mortality rate in this group was 5 per cent; three deaths were due directly or indirectly to horses and two deaths were caused by bulls (table 5). The youngest person injured was 3 years old and the oldest was 85. The average age for this group of patients was 46 years (table 3). Although the bull is generally considered the most dangerous animal on the farm, it may be seen in table 6 that the horse accounts for most of the livestock accidents; 66 of the 104 accidents were due directly or indirectly to horses. There are several reasons for this high incidence. First of all there are more horses than there are bulls on the farm and the farmer handles them oftener in his daily work. When handling a bull the farmer usually treats him with respect, but he is likely to become careless in the handling of a horse. Table 6 reveals that fractures were the main injuries received in accidents caused by livestock. In addition there were 3 cases of transverse myelitis and 51 miscellaneous injuries.

Table 5.—*Deaths at Clinic from Accidents on the Farm, 1935-1943 Inclusive*

Accident	Patient's Age, Yrs.	Injury	Cause of Death
Fall			
On pitchfork handle	47	Perforating perineal wound	Peritonitis
On ground..........	53	Lacerated knee	Gas gangrene
Against radiator....	83	Fractured ribs	Bronchopneumonia
On pitchfork handle	63	Perforating perineal wound	Peritonitis
On pitchfork handle	17	Perforating perineal wound	Peritonitis
From haystack.....	46	Fractured cervical vertebra with transverse myelitis	Pneumonia
Downstairs..........	63	Fractured humerus	Pulmonary embolus
Downstairs..........	62	Fractured cervical vertebra with transverse myelitis	Paralysis
Downstairs..........	60	Fractured cervical vertebra with transverse myelitis	Shock
Run over by horse-drawn binder	44	Multiple fractures	Shock
Kicked by horse........	69	Fractured mandible and maxilla	Bronchopneumonia
Kicked by horse........	10	Fractured skull	Meningitis
Attacked by bull.......	56	Fractured cervical vertebra with transverse myelitis	Paralysis
Attacked by bull.......	44	Fractured cervical vertebra with transverse myelitis	Paralysis
Lighting stove with kerosene	83	Burned 75 per cent of body	Shock
Clothes caught fire from lantern	70	Burned 50 per cent of body	Shock
Struck by falling tree..	25	Transverse myelitis	Shock
Scratched with barbed wire	71	Laceration of scrotum	Gangrene and pulmonary embolus

Miscellaneous Accidents.—Seventy-seven accidents in this series were caused by the ax, by falling trees or by a group of unclassifiable causes (table 7). Again, fractures were the most frequent injury; traumatic amputations occurred in 2 cases and transverse myelitis in 4.

There were 15 cases of burns in this series of accidents with two hospital deaths, a mortality rate of 13 per hundred accidents (table 1). Most of these burns occurred through the ill advised use of kerosene or gasoline in the starting of a fire or through the explosion of a stove or bottled gas. The youngest person burned was 7 months old and the oldest was 83 years; the average age for the group was 35 years (table 3).

In the entire group of 575 accidents in this series the injuries sustained consisted of 396 fractures, 65 traumatic amputations, 25 instances of transverse myelitis, 9 of perforating perineal wounds, 7 avulsions of the skin of the penis and scrotum and 208 miscellaneous injuries (table 8). Some of the patients had more than 1 fracture or miscellaneous injury. The youngest person involved in an accident on the farm in this series was aged 7 months, while the oldest was aged 85 years. The average age in the entire group was 39 years (table 3). Although these accidents cover almost the entire span of human life, the average person is injured and suffers death or a permanent disability at the age when he is the most productive. The problem, therefore, is an economic one as well as humanitarian. In this series of cases there were eighteen deaths, a mortality rate of 3 per hundred cases (table 1). This does not mean that these were the only deaths in the counties around the clinic which were due to farm accidents during this nine year period. These eighteen deaths represent only those patients who had sustained an injury on the farm and died after reaching the Mayo Clinic. Other persons died before medical aid could be given by any physician, and some may have died after receiving medical care elsewhere.

COMMENT

Complete statistics on farm accidents and their mortality rate are impossible to obtain because not all these accidents are reported. The National Safety Council[1] reported 17,500 accidental deaths due to occupation and 1,800,000 occupational injuries in the year 1944. Of these deaths 4,300, or about 25 per cent of all occupational deaths, were those of farmers or ranchers who were killed at work. More accidental deaths occurred in agriculture in that year than in any of the other five major industrial groups. In addition there were 900,000 nonfatal farm home accidents and 225,000 nonfatal farm work accidents in 1944. Also 14,800 farm residents were accidentally killed in 1944,

---

[1] Accident Facts, Chicago, National Safety Council, Inc., 1945.

and this total is exclusive of those killed in motor vehicle accidents.

By using this report of the National Safety Council as a basis (and this report showed a decrease of 5 per cent from previous years) it can be estimated that approximately 38,700 farmers were killed at work, 133,200 farm residents were killed accidentally and 10,125,000 nonfatal farm home and work accidents occurred in the United States during the nine years covered by our present report.

The problem of the farm accident is a serious one. Although today some effort is being directed toward reducing such accidents, more needs to be done. Prevention of these accidents is by far the best treatment of them, and the first step in this prevention is in educating the farmer in methods of safety. Children, for instance, have no more right to be near or on a piece of operating farm equipment than around a punch press or on a moving locomotive, and yet they are permitted to be there daily.

SUMMARY

Five hundred and seventy-five accidents on the farm caused the persons injured to come to the Mayo Clinic in the nine years from 1935 to 1943 inclusive. Most of the injuries were due to falls, farm machinery and livestock. Most of the persons when injured were in their most productive years. Accurate statistics of farm accidents are not available, but the mortality rate from them is known to be extremely high. Other industries have reduced their accident rate by eliminating hazards as much as possible and by educating their employees in the safe ways of handling machinery. An educational program for the farmer is the first step in decreasing the number of accidents on the farm.

ABSTRACT OF DISCUSSION

Dr. Hugh T. Jones, Los Angeles: Drs. Young and Ghormley are to be commended for bringing this problem of farm accidents before the medical profession and the proper civic and farm organizations. It is natural during the war years that emphasis has been placed on the problems connected with industrial injuries. The law compels insurance of these men in industry, and insurance companies have been helpful in the prevention of industrial injuries and accidents. Farm laborers in general throughout the United States have little insurance protection, and statistics on farm injuries are meager. At first thought we in California are likely to think that without the many corn pickers and corn shredders of the Middle West we enjoy a certain immunity to farm accidents. On second thought, we know that we have ladders, wagons, trucks, stairs for serious falls, thrashing and mowing machines with moving parts, livestock, barbed wire, falling trees and accidents with pitchforks, all of which carry a threat to safety. The ever prevalent gas and tetanus bacilli are especially prevalent in farming communities. About a month ago I attended a meeting of the California Safety Council in Los Angeles. I know that at present its main concern is with the terrible traffic toll. However, I am sure that this council could be helpful in the problem of farm accidents if given the proper information. A review of hazards in each state under the direction of the safety council in each state seems proper, and the cooperation of the medical profession with the various safety councils also seems important to me. Before we are through, it is likely that some plan of insurance for farm workers will be arranged. Then, with better statistics, better plans of prevention can be instituted. In the meantime, such educational work as Dr. Young and Dr. Ghormley are carrying out will be helpful in bringing about the needed change.

Dr. Douglas D. Dickson, Oakland, Calif.: Drs. Young and Ghormley are to be commended on their excellent survey of farm accidents and their study of the patients cared for at the Mayo Clinic during this nine year period. In making an effort to investigate the origin of such accidents, one finds that data are not available except in very few states. Their exhibit illustrates beautifully the extent and the importance of this problem. I should like to emphasize the statement with regard to the fact that more accidental deaths occur in agriculture than in any of the other five major industrial groups. Startling facts are also revealed by a recent report of the National Safety Council. It reports that agriculture, with more workers than any other industrial group, had a death rate of 53 per hundred thousand workers. In all other industrial groups the rate was 31 per hundred thousand. In males alone only two causes of death rank above accidents, namely heart disease and cancer. In other words, accidents account for more deaths than such common diseases as pneumonia, tuberculosis and nephritis. In a survey made in 1945 in the state of Wisconsin, people on thirty-five farms were interviewed, revealing that one out of every nine full time operated farms was the scene of a farm work accident resulting in either loss of time or, in many instances, loss of life. Dr. Young has already pointed out that a large factor in the causation of many accidents is that farmers use machinery who are not trained in the use of such equipment and that they are not highly skilled and trained in such work. Their equipment in many instances is poor and in a poor state of repair. Other industries, by means of study and educational programs, have eliminated hazards to a great extent, accounting for these startling figures. Large industrial concerns come under the jurisdictions of federal and state inspections as a means of instituting safety devices and organized educational programs. The National Safety Council should be accredited for its work in this educational program.

Dr. Hugh H. Young, Rochester Minn.: I want to thank both Dr. Jones and Dr. Dickson for their discussion and to make one other statement. You will note that in the groups that Dr. Ghormley and I discussed there were a number of young children who were hurt. These children were hurt while riding on pieces of farm equipment. That same farmer, in another industry, operating a punch press, for instance, would not be allowed to bring his child to work with him and he would not think of doing so. I believe that this is one place where we can make an effort to reduce the number of accidents in children.

Hoarseness in Children.—One subject in laryngology that has not received sufficient attention is hoarseness or other faulty voice conditions in preadolescents or young adolescents. We all seem to expect to hear the "cracked voice" in boys and have a tendency to laugh it off and to assume that the lowering of the voice in girls is just part of the transition phase. It is not fair to these children to take this attitude, and it is our duty to investigate these conditions, as many times there are associated remedial causes which should be eliminated.—White, Francis W.: Some Causes of Hoarseness in Children, *Ann. Otol., Rhin. & Laryng.* **55**:537 (Sept.) 1946.

INDUSTRIAL OPHTHALMOLOGY AS OF 1946

HEDWIG S. KUHN, M.D.
Hammond, Indiana

Prior to the war the field of industrial ophthalmology was actually a subdivision of the field of industrial hygiene, strange as that may seem now. The emphasis was entirely on treatment of injuries, traumatic surgery, study in prevention and treatment of toxic damage to the external eye, or by systemic effect producing intraocular pathologic change, and, finally, the study of medicolegal procedures and workmen's compensation rules and regulations. Actually the term industrial ophthalmology is already obsolete, the more correct term being occupational ophthalmology.

Some phases of work held to be within the scope of occupational ophthalmology are the following:

1. New visual testing technics have been devised to provide accurate information whereby physical capacities (eyes in this instance) are matched to job demands.

2. Modern concepts of corrective procedures include a thorough knowledge of both actual work distances and mechanical details of job demands. Here the future use of special occupational glasses (not goggles) in textile and hosiery industries in particular gives promise of being a tremendous contribution to visual comfort, increased production and the solution of many industrial relations problems.

3. A development of a new type of fact finding approach in the handling of properly recorded visual statistics by using modern punch card analytical procedures with resulting profiles and patterns of visual performance has been the contribution in particular of Professor Joseph Tiffin and his staff in their brilliant work. Here the nonmedical man has put into the hands of medical people a new and significant tool.

4. Lagging somewhat in understanding and in outlined procedures is the development of closer relationships between top management and the medical profession—a "must" if industrial eye problems are really to become a part of the responsibility of those ophthalmologists who are interested.

5. Active interest in the field of safety to eyes and to individuals from eyes (body accidents due to visual defects) and the understanding of protective equipment is bridging the previous gap between the work of safety engineers and that of professional ophthalmic services.

6. An understanding of illumination in industry (as different from illumination in schools or in homes) and the use of color in reducing visual fatigue is now being developed by illumination research engineers (not salesmen) and by Faber Birren, the du Ponts and others.

7. An adaptable, elastic and yet definite understanding of what constitutes a minimum industrial eye service for either a large or a small plant is the phase of our subject that draws together all other phases into a program.

8. There is now also recognition that our medical schools, both in the undergraduate and in the graduate years, need to incorporate courses with full information of all problems indicated. Research work in scientific centers will broaden.

9. Tied to the lack of present educational opportunities for ophthalmologists interested in industrial work is one stark question that must be faced, by this group in particular; that is, how many ophthalmologists are going to be interested in industrial ophthalmologic work as it is understood to be of this year 1946? Are ophthalmologists aware that industry will demand service, including all or part of such services as we are discussing? What is or will be our position in carrying through? Can we "deliver"? Are we willing to play a part or not; if so, what part?

10. What are some of the immediate problems where knowledge is meager and further research work is urgent, such as special near point complications, new chemical hazards, a better understanding of ultraviolet and infra-red hazards and training of special personnel to carry out details of industrial eye programs?

Of greatest importance is a thorough knowledge of a few highlighted angles.

VISUAL MASS TESTING TECHNICS

The first step taken because of pressure for war production was research underlying the subsequent development of various mass testing instruments and technics. It is important here to emphasize that the continued use of the phrase "visual screening" is both inaccurate and psychologically inadvisable. In the more distant past, job applicants and labor in general have felt (and formerly rightly so) that preemployment visual tests (as well as physical examinations) were a procedure utilized to screen out, i. e. refuse jobs to, applicants. Actually, visual testing procedures as developed do the opposite. They are the best insurance of acceptance of an applicant and his proper placement. Also, the discovery of substandard visual skills among payroll employees in a properly conducted visual survey has made possible the correction of many visual defects and the continuance of jobs formerly in jeopardy.

Proper testing of applicants can be and is being done either within industry itself or in the professional consultant's office. Visual surveys of any given plant must, of course, be done not only in the plant but as close to the job as is physically possible. In the past (and too often even now) the only eye examination given an applicant was the Snellen distant vision test with the use of an improperly lighted wall chart by an indifferently trained person. In some instances such tests are made in the waiting room over the heads of the applicants who, if they had not already memorized the chart, have ample opportunity to do so. In using the battery tests, malingering is reduced to a minimum and the person is given an accurate series of tests including much more than distance acuity. These tests, usually best given in the employment or personnel offices by specially trained lay technicians, are tests recording visual skills. They are not eye examinations and are never thought of as such. They belong in the category of aptitude tests. They point the road to proper job patterns and lead the way to the doctor's office and timely corrective procedures.

There are a number of so-called battery instruments: The telebinocular has been used successfully in many industries. When the medical director or professional consultant is sufficiently interested, valuable information can be secured. By changing the type and sequence of the targets, modifying the record blanks and reevalu-

---

Read before the Section on Ophthalmology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

ating the conclusions, our staff uses this instrument. However, in many instances the instrument seems to have been sold as a commodity by salesmen and left on some one's desk for industry to struggle with.

The Ortho-Rater was developed by the Bausch and Lomb Optical Company. This instrument and the follow through program met not only some extremely critical war production needs but some even more urgent military needs. The instrument records in detail those visual skills thought important now. New tests can be added as the need is demonstrated and as our knowledge increases. The training of the technician operating the instrument, the breakdown of the recorded data into practical job standards, the support and assistance given to personnel, employment and medical staffs, the continuing scientific research made possible through the services of the Purdue Industrial Visual Institute, makes the program (the instrument being a mere tool) a great step forward for industry and for us. The institute faculty includes medical members.

The Sight-Screener, developed by Paul Boeder, scientific director of the American Optical Company, is another instrument which will play a part in this field. To date, however, there has not been developed the supporting follow through we should like to see for the evaluation of data revealed or for the continuing research and guidance needed by industry and its professional consultants. It is to be hoped that this phase of the contribution of the American Optical Company will be developed. There is always a need for various types of testing equipment and always plenty of room for further research.

Visual data important to secure and record for each employee, in whatever way is practical, include (1) distance acuity with and without correction, (2) near acuity with and without correction, (3) phorias for distance and near, (4) stereopsis for distance and near and, (5) color appreciation. The medical profession is most interested (as far as acuity goes) in a record of acuity for distance without any correction. This is essential for future reference and for possible medicolegal purposes. On the other hand, personnel, placement and training officers are most interested in the vision of an employee with the correction he is actually wearing, that being the pair of eyes with which that employee is actually operating and producing. Both records are essential.

All data secured in a battery of tests confined to one instrument can also be obtained in one's private office by a series of individual tests: projection charts for distance acuity, Maddox rod or prisms for muscle imbalances, Verhoeff stereoscope for depth perception, Ishihara color chart and the various near vision acuity cards. It might be well here to emphasize the appalling lack of standardized, accurate and reliable near vision acuity test. The ordinary fingermarked reading card, in its many variables, and an assortment of substitutions such as the Lebensholm chart and the Guibor chart are the only technical equipment the professional man has with which to record exact near vision data.

SPECIAL CORRECTIVE PROCEDURES

To date, substandard visual skills and actual acuity defects are only in part correctible. It is important that industry itself understand this and that we do also. In most instances one can correct a refractive error. Such a correction given to an individual for his occupational needs must be based on his actual work distances. If these distances are identical with his personal needs, the prescriptions are identical; if not, he will require two pairs of glasses. Unusual job demands, for instance, are looping (work at 8 inches), blueprint and layout work (24 to 36 inches) or inspection of hot steel on moving rolls (at a distance of 4 feet to 6 inches). The best refractive skill is required to correct properly for most occupations, but this skill can be tragically ineffective unless actual work operations and distances have been witnessed by the refractionist. A high hyperope doing near vision inspection of great detail may require not only more plus but perhaps a prism base-in, while a young myope working at 8 inches would certainly get into difficulties if given a full minus correction for use at 8 inches. Workers seldom can reliably describe their work distances. If unable to visit local industries, one may need to ask the employee to bring a memorandum from the plant giving exact work distance. Industrial refractions should be supplemented by a fundus examination, notation of any external pathologic conditions and the taking of rough form fields. Here a note of warning is indicated: the concept of specific job correction can be exploited by unethical or income-seeking services; all benefit in vitally needed cases will be erased if the truism is made into a racket.

While refractive errors are in the main correctible, a lack of color sense and complete lack of stereopsis are not. There are some phorias (exophoria for near especially) that are definitely amenable to orthoptics. In cases in which the exophoria is producing symptoms and if orthoptic training is available, such cases (being correctible) should be referred. However, nothing is more destructive to confidence in an eye program than (as matters stand today) to (1) send workers lacking stereopsis or color vision or minor muscle imbalances out for correction only to have these men told "there is nothing wrong with you" or (2) to send out persons with exophoria and persons whom orthoptics could help when orthoptic training facilities do not exist. Such blundering practices do not "make friends and influence people."

STATISTICAL ANALYSIS OF VISUAL DATA

Perhaps the greatest contribution is the fact finding approach as developed at Purdue University and the type of thorough research work of Berens and Hardy and Rand. Medical people are definitely allergic to the vocabulary of statisticians and to any challenge made to their clinical and intuitive evaluation. It requires an earnest and sincere effort to keep an open mind to this phase of industrial eye problems if one is to move forward with the vanguard of thinking and to profit by the consistent drive to validate previously presumed "facts." An instance is our conception that 20/20 vision is "normal." In analyzing acuity tests in a plant of 6,800 employees, this is shown to be incorrect; 54.9 per cent had a vision of 20/15.

Statistical study of visual data is already making it possible to develop formulas whereby job patterns (predicted visual skills) can be set up to match visual job demands. Such an approach (which supplants the old trial and error or survival of the fittest procedure) is not yet easy for some of us to swallow. I also was allergic to this type of theoretical thinking on the part of so-called "laymen," who proceed then to lay down boundaries for us, though applied psychologists and statisticians with Ph.D. degrees are experts in their own right. The consistent revelation of results in line with predictions has forced on me the conviction that we, as physicians, dare not waste this valuable new tool by wilful resistance and can overcome our reluctance even to the point of eager enthusiasm.

TOP MANAGEMENT AND THE PHYSICIAN

In the past the ophthalmologist has received the employee with a perforating injury of the eye in the hospital; he has treated lime burns in his office; he has diagnosed an optic atrophy in a man exposed to lead or methyl alcohol poisoning and found the toxic source. But as of 1946 he holds a position parallel to that of the metallurgist or research director of an industry. When a steel plant gets a batch of steel that does not behave properly, the problem is thrown into the lap of the metallurgist and his laboratory. Industry is now throwing problems connected with "visual bottlenecks" of every kind into our laps. We in our laboratories have to learn how to find the answers. The problem given us may be tied to the labor turnover found among loopers (who number 200,000 in the United States)—the turnover is actually almost entirely due to visual fatigue, pain and discomfort. On the other hand, our problem may be one of alerting a plant when an isolated case of epidemic keratoconjunctivitis presents.

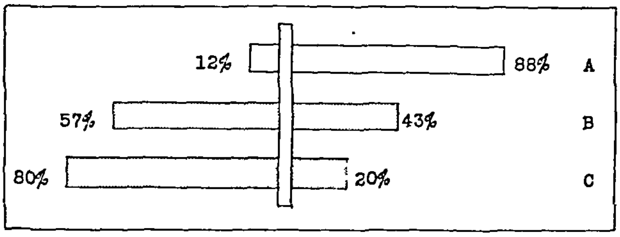

Fig. 1.—Depth related to safety (from "Spotting Accident Prone Workers by Vision Tests," Factory Management and Maintenance, June 1945).

When the professional eye consultant is asked by top management to suggest improvements in the handling of their eye problems, it is essential that we seek to understand industry: their personnel structure, no two plants being alike, the interrelationship between departments, each jealous of its own prerogative, and the special idiosyncrasies of plants having absentee control from a mother plant where perhaps some diehard resists change. We do need to throw our academic reserve overboard. No doctor loses caste with management or the workers if he drops the use of sixty-four dollar words and learns the vernacular of the men that he is or will be working with. It is usually best to work out an industrial eye program step by step and not to advocate a sudden "all or nothing" proposal.

An eminent ophthalmologist who has contributed much to industrial eye work made the flat statement once that it was impossible to work with unions. It undoubtedly was difficult to do so in the community where this colleague practices but that is not true in all parts of the country or for every union or for every ophthalmologist. There are many industries in which it is far easier to work with the unions than with management. In one instance in my experience the entire ophthalmologic program (after being set up at management's request) was backed and supported by the union, and mandatory goggles protection was policed by the union itself. Real salesmanship is required in working with industry, a good deal of give and take. The many and varied challenges—no two plants the same, no two programs the same—are part of the exciting returns made.

SAFETY IN EYES

While plans for the protection of the eye have in the past been mainly in the hands of a lay safety director, the ophthalmologist is increasingly concerned with what the actual hazards to eyes are and the protective equipment required for each type of hazard; and he recognizes also the hazards from eyes (due to defective sight).

We have been inclined to say empirically that stereopsis, for example, is necessary for safety on certain jobs—arriving at this opinion by process of logic only. Instead, we need to seek evidence from surveys and experiments conducted with proper controls. Our logic relative to stereopsis and accidents turned out to be good for certain jobs, as shown in figure 1. In a metal industry three groups of employees were studied separately over the same period of time, group A having had no accidents, group B having had a high frequency of minor injuries and group C having had serious injuries. This chart shows that of group C (serious injuries) only 20 per cent scored above average on this test. Such studies were conducted by N. Frank Stump, Ph.D., at Revere Copper and Brass Inc.

Such relations that can be demonstrated between accidents and inefficient visual performance illustrate the method by which the fact finding approach is conducted. Dr. Stump established the desirable pattern of visual skills on a battery of tests for accident free workers on those jobs that he studied. For purpose of classification of employees as hazardous or accident free, it was determined which workers qualify on all, on some or on none of these tests. From such tests it was possible to predict which new employees would accumulate the largest number of accidents. New employees whose vision deviated greatly from the visual standard, logic would tell us, should have the largest accumulation of accidents, and they did according to the facts. Figure 2 shows the results. In the first eighteen days of employment those with the greatest deviation from the optimum visual pattern had a 61 per cent accumulation of accidents, those with moderate deviation a 29 per cent accumulation and those with negligible deviation an 11 per cent accumulation—a difference of 50 per cent between the extreme groups. But again these sticklers for real validation said, "These groups will equalize if the follow-up is continued over a long period of time." This was not the case according to facts, not according to the results shown in figure 3. Over a thirty-eight day period these same three groups

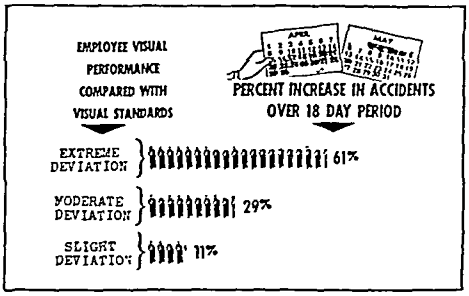

Fig. 2.—Ortho-Rater tests related to safety. (Figures 2 and 3 are from "Four Points to Safety," Safety Engineering, September 1945.)

had 106 per cent accumulation, 43 per cent and 31 per cent. There is a difference of 75 per cent between the extreme groups. This illustrates a technic of using cold facts and substantiating them—management's language.

A previous study by Purdue University on 8,000 workers in a steel mill revealed that patients with "serious injury" tend to overconverge at far and underconverge at near. Figure 4 shows that among those with the greatest change in convergence from far to near 4 per cent had had serious accidents, while among those with the least change in convergence nearly 9 per cent had had serious accidents, a ratio of more than 2 to 1.

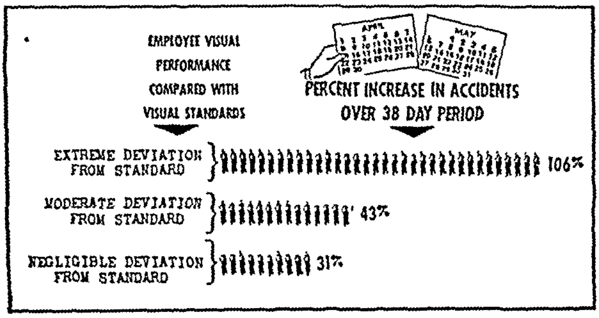

Fig. 3.—Ortho-Rater tests related to safety.

When management invites me to talk to the foremen, to safety committees, to shop stewards, I accept, emphasizing the need of proper maintenance, adjusting and servicing of goggles (especially prescription goggles), thus insuring greater success to a program of eye safety. I find this to be an enlightening experience, often an exciting and amusing one. True, one needs to have a sense of humor, a real understanding of all the facts involved (no bluffing) and a fairly thick skin to toss back effective answers to questions coming from such an audience.

At a special conference in October in which all parties concerned will be represented, an effort will be made to formulate a basic policy and definite principles with reference to the sale of goggles, bargains and rebates, as well as proper methods for maintenance, adjusting and dispensing. It is earnestly hoped that existing unethical and improper practices will thereby be corrected.

ILLUMINATION AND COLOR

It is important to mention in passing, as it belongs in one's thinking of an industrial ophthalmologic program, that the field of illumination and the use of color in industry have moved forward with great strides. Fluorescent lighting, color contrasts, research on foot-candles required, so-called brightness contrasts and ratios, and the use of directional plus indirect lighting are a part of industrial seeing.

MINIMUM INDUSTRIAL EYE SERVICE

The minimum industrial eye needs of a large plant and of a small plant are identical. The steps in setting up any industrial eye program includes variables of the following:

1. *One should make a leisurely tour of the industry* in question. Nothing can be effectively planned or carried through to completion without this step. It has proved best to be accompanied by some one who understands plant operations and individual machines and their function. Neither the medical director of a large plant nor the top management makes the best guide.

2. It is valuable to take along a check list which can be devised very simply to suit one's own needs. Prior to the visit, management gives one a list of the name of each operation, the department and the job number. Moving from one job to another, one can check off what seems to be of greatest importance (visually speaking). For instance, it would seem that a turret lathe operator needs excellent distance acuity at his multiple work distances, that coordination and muscle balance are probably an important factor, that there are certain hazards such as flying particles and that a certain type of illumination is indicated. This does not provide the proper basis for setting up *scientific visual standards* for any job. This is one's personal memorandum to understanding and for the recommending of the broad foundation for an eye program. It is one's "know how."

3. Recommendations for choice of type of visual testing procedures, for preemployment and preplacement examinations of the eye, can then be based on one's knowledge of what seems to be the most urgent need. Here judgment is required, and sometimes one acquires *judgment the hard way.*

4. The compilation of statistical data secured by visual tests is an integral part of the usefulness of a program.

5. The type of procedure to be employed in establishing a corrective plan for each individual plant is based on the statistical findings and on local professional interest and skill.

6. When management pays for having the eyes of employees refracted, one must decide where the refraction is best made and what schedule is best suited to the plant and to the examiner. Community practices, urgency of needs, geographic location of plant, type and quality of available professional help—all are details to be considered.

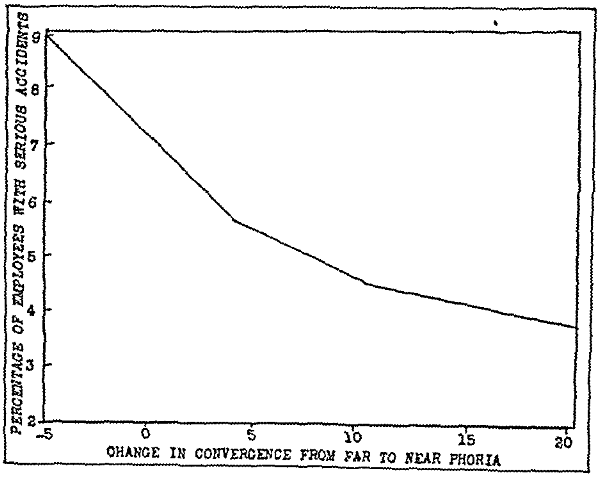

Fig. 4.—Relation between phorias and serious accidents (statistics from Purdue University).

7. Perhaps the most important part of an industrial eye program is the follow up and follow through. Just to test eyes, compile figures, refract eyes, order goggles or occupational glasses and stop there is to have produced a sterile, lifeless thing: one should keep interest alive, show results, find even better ways.

SOME SPECIAL SPECIFIC PROBLEMS IN PROCESS OF STUDY AND RESEARCH

1. One of the great fields for further research in industrial eye problems is the study of near vision visual performance. Here the great textile industries will be most greatly benefited, as will radar assembly and filament inspection and similar operations. Also the field is wide open for improved accuracy in testing equipment for use in examination of near vision function made in the office.

2. Another no man's land is in the field of radiation. Research work was done long ago by Dr. Verhoeff in his fundamental treatise and more recently by Drs. Cogan, Drinker and Kutscher. We, as ophthalmologists, are poorly equipped with facts when we are called on to testify before an industrial commission hearing the evidence for loss of vision due to infra-red or ultraviolet injury. Practical research done by and inside industry, studying variables in amount of radiation of actual welding operations, amount of energy effective at different work distances, findings with and without protection to the eye as actually used in a plant and not only so-called recommended procedures, the determination of exposure to infra-red in foundries, the part played by element of time, actual amounts of infra-red found—all this is urgently in need of further investigation and is in process of being organized. The lack of intelligence in radiation problems is revealed in the workmen's compensation cases carried to the highest court. It seems incredible but considerations which have proceeded through long laborious hours of discussion, hearing of evidence and weighing of facts all rest on our exceedingly flimsy foundation. Five cases carried to high courts were found to be concerned with strange side issues:

Case 1.—The main points involved and stressed are whether the flash sustained from another worker nearby was to be considered an accident or an occupational disease (Colorado Supreme Court).

Case 2.—In a flash case heard in 1929 the worker was given temporary total disability. In 1935 he entered a claim that the opposite eye was involved with loss of vision due to the 1929 exposure. Here attention was focused on whether the plaintiff had the legal right for a rehearing (Ohio).

Case 3.—The case of sudden loss of vision in the only good eye of a worker who had been exposed thirty minutes to the glare of an acetylene torch was carried to a high court, in spite of the presence of considerable illness, including syphilis This did not prevent the award of total loss (state of Louisiana).

Case 4.—A case in which a moving picture operator exposed to the glare of carbon arcs claimed and received total disability on the basis of occupational disease producing the pathologic condition of cataract (New York). (Whether or not this person could have had normal vision with cataract extraction did not seem to figure in the picture at all.)

Case 5.—A motor tester exposed to a flash 3 feet away, who was already blind in his right eye as the result of glaucoma, claimed and was granted total disability and blindness in the left eye from a flash also (state of Pennsylvania).

3. Will ophthalmologists be interested in meeting the challenge of industrial eye problems? If so, can they meet it? The greatest interest that is being shown at the present time is among the younger men being discharged from the service. I hope that their interest will change the figures revealed by a survey two years ago. The Joint Committee of Industrial Ophthalmology asked the National Society for the Prevention of Blindness to send questionnaires to the ophthalmologists in this country. There are a total of 6,182 ophthalmologists (this group including eye, ear, nose and throat men). Questionnaires went out to 5,511. Returns were received from 559, and of these 399 (71 per cent) expressed an interest in enlarging their industrial practice. Of these 259 (44 per cent) indicated that they were familiar with eye hazards and visual requirements of plant operations. This is certainly a drop in the bucket. Even more significant is the fact that 352 (63 per cent) of these believe that individual refractions should be done by them and in their offices. We must, in line with the needs of industry and our own multiple problems, evaluate the use of the potential talents of optometrists in arranging a refractive service for industry. Many well trained ethical optometrists demonstrated their ability on Army and Navy assignments. Others have demonstrated their understanding of industrial eye problems, refracting and guiding an eye protection program in the critical war industries in this country. Programs such as were set up at Sperry Gyroscope, one of the outstanding industrial eye programs in this country, may well form the pattern that we shall need to develop. This phase of eye service to industry demands our earnest attention.

4. The programs set up by the War Production Board in cooperation with many government agencies, and under the sponsorship of the National Society for the Prevention of Blindness, revealed the present practices of industry. While only 10 per cent of the plants receiving questionnaires returned them, these 283 concerns totaled almost a million workers and the size of the plants varied from one employing 23 to one employing 65,000. As industries willing to reveal their statistics to a government agency would be among those who had the best practices, the facts shown here were most significant and indicate the enormous problems which face industry. I do urge that industry not be stimulated further, at the moment, to do something (other than modernizing protection of the eye and job placement) about its eye problems until provision has been made to meet the innumerable requests for properly training professional help.

5. The increasing need for professional help as expressed here leads directly into the need for increasing educational opportunities. A year ago 70 per cent of the approved medical schools sent the heads of their departments of ophthalmology to the Columbia course designed to acquaint them with the scope and content of industrial ophthalmology. This is a definite expression of interest by our medical schools which, though sadly tardy, gives recognition to the urgent needs of today.

6. Participation of ophthalmologists in planned medical conventions, safety conventions, seminars of industrial nurses, personnel and industrial relations groups, are all a part of the training of tomorrow's industrial ophthalmologists. In line with this also is the reading of much literature outside the medical journals and publications. Some of the best articles dealing with industrial eye problems have been published by management, personnel and safety periodicals as well as by journals of applied psychology. It is due to this great need for informal reports of "plant experiences," which are akin to case histories, that the Joint Committee is gathering together all available material for publication in a number of our medical journals.

CONCLUSION

It has been my earnest hope that by spotlighting just a few of the problems lying within the field of occupational ophthalmology, many ophthalmologists will catch fire and take hold—some of the younger men seem more than eager. The need is great; it is a part of the basic thinking in the era of atomic energy; it is exciting and fascinating work; some previously unorthodox procedures may need to be made good and used. It is—all of it—our challenge.

112 Rimbach Street.

ABSTRACT OF DISCUSSION

Dr. Derrick T. Vail, Chicago: Dr. Kuhn has mentioned the clamor that industry is making on our doors, seeking help in the solution of its problems. The help is forthcoming in many fields. She touched on the magnificent work of Professor Tiffen and his punchcard system of job analysis in relation to ocular phases. But we are handicapped by our relatively small number. Dr. Cordes in his chairman's address summarized the past difficulties and the future possibilities, but the fact remains that at the moment we are caught short, so short that the training facilities are desperately handicapped and the number of ophthalmologists is at a minimum to answer the demands that are thrown on us from all sides. Dr. Parker Heath presented before the American Ophthalmological Society a scheme for training ophthalmic technicians under medical direction, which I think may be part of the answer to our difficulties. It is of interest to note that the American Ophthalmological Society endorsed this scheme unanimously, and it is my understanding that there will be something said about this particular phase before the section. However, the plan is to develop medical technicians who will be a real aid to ophthalmologists, and certainly industry will be able to use these workers under the direction of a competent consulting ophthalmologist who will have under his direction a number of industries in his particular area. That is one way of answering the need for personnel. Dr. Kuhn mentioned optometrists, particularly the decent fellows —and there are a number of them. We saw them in the Army. They were most useful and most valuable members of the armed forces. Without the use of these optometrists the overwhelming problem encountered by the Army would have been hopelessly bogged down. There is no reason that I can see why these optometrists cannot be used under the supervision of ophthalmologists in a proper way, so that this great work of industrial vision and industrial ocular problems can be carried out to a better condition. The last phase is the teaching of industrial ophthalmology in our medical schools. The point faced by us who are charged with the responsibility of teaching departments is whether we should devote any time to this subject in the undergraduate course or whether we should conserve our efforts in this line and direct them toward teaching in the postgraduate courses. A great deal of thought and attention should be devoted to this study. I am at the moment unable to make up my mind as to just what is the best approach to this problem from a teacher's point of view.

Dr. A. C. Dick, San Diego, Calif.: All medically trained persons must become more cognizant of the meaning and importance of healthy industry to the stability of our form and manner of living together as a people. This will imply that the average doctor will have to spare a little time from the sanctuary of his office to learn more of the mechanical and human aspects of production matters. Certainly it will imply that he shall look on his average patient in a new light. By thinking of some of these matters in this way the doctor will make an enormous contribution to industrial efficiency, community stability and political sanity. Industry needs his help and during the war has come to recognize this need more definitely than ever before. When this call for help comes, as it will, what are the chances that it can be met? In general, the record of the American medical profession is such that we could state unequivically that the answer would be in the affirmative. In highly integrated industry the health needs of the employee cannot be met without the assistance of highly trained specialists in the various fields of medicine. New and more effective procedures and processes have created new demands on the physical and mental adaptability of the worker. Therefore one who may have specialized in the field of ophthalmology will have received a certain insulation from the field of general medicine; but he has become, by reason of his special ability, much more intimately exposed to industrial or occupational medicine. He is the one on whom the industrial world will call for solution of its sight and seeing problems, and incidentally these are becoming of greater proportionate significance daily. There is a significant need for medical specialists industrially. Whatever effort is put forth will contribute both directly and indirectly to more than a correction of an isolated condition. Ophthalmologists, like other specialists, can contribute most if they can conceive of industry as a community function and translate their special knowledge in terms comprehensible and useful to the average citizen who works. For these reasons it has been a pleasure to be able to discuss this paper by Dr. Kuhn, for it contains material of more than passing significance.

Dr. E. H. Cary, Dallas, Texas: Dr. Vail raised the point as to what could be done with the undergraduate. The trouble with medical education today is that a vast amount of information is to be given to medical students and we have attempted to give it to them in thirty-two weeks. With all the new knowledge to be presented to medical students, the specialties have been pushed aside. The student must be a well informed man in surgery, medicine, obstetrics and gynecology and what are known as fundamental subjects. In the Southwestern Medical College we recently discussed, and I think we shall put it into effect, a program for extending the medical course to forty weeks for the first year, forty-six weeks for the second year, forty-six weeks for the third year and forty weeks for the senior year. This permits the men who graduate to take their board examinations and enter hospitals as interns. But in extending the course we shall recapture some of the time which is so very much needed and which is so essential to give the specialists an opportunity to give the young medical man a general training which is worth while. Although a technician, such as an optometrist, may be in some instances capable of refracting an eye without having it properly relaxed, I cannot concede that he has the knowledge that is essential to aid accurately the people in industry. I feel that we should adopt a more extensive course, because most of our medical schools have full time teachers as professors and they have had their salaries materially increased as a result of the accelerated program. I take the position that those gentlemen should now take the opportunity to amplify the course in medicine so that it will proceed to the extent of some 178 weeks before graduation instead of 128. Not only will you have a fairly good doctor, a general practitioner, but if you extend the opportunity for the student so that he will have the clinical advantages and the clinical opportunities with the teachers in ophthalmology and other special subjects which we classify as specialties, you will have a well rounded man to go into industry with at least sufficient knowledge to be useful. I do not expect ever to make a real specialist of any man, because I have always known that first a man has to be thoroughly trained through his hospital internship. It may be general practice for some but at least following a wide experience in special hospitals to get special knowledge. However, it would be impossible ever to supply the number of men that have been spoken of this morning through the process which we have always had in mind and always adopted. If we can extend the course as I have outlined, I believe we can supply to industry men who will be far more capable of meeting the issues that might arise and doing it much more satisfactorily for the people who are to be served than we could do it through a program of using technicians.

Dr. Hedwig S. Kuhn, Hammond, Ind.: I want to express gratitude for the support that has been given to the Joint Committee on Industrial Ophthalmology. I report the glad news of progress being made in England and I hope that Sir Stewart Duke-Elder will help us in joining hands to accelerate further the solution of our industrial ophthalmologic problems.

TREATMENT OF TUBERCULOSIS WITH STREPTOMYCIN

A Summary of Observations on One Hundred Cases

H. CORWIN HINSHAW, M.D., Ph.D.
WILLIAM H. FELDMAN, D.V.M.
Rochester, Minn.
and
KARL H. PFUETZE, M.D.
Cannon Falls, Minn.

The search for drugs effective in treatment of tuberculosis has long been under way, but significant progress toward a practical goal was not achieved until the modern era of chemotherapy reawakened interest in the subject. For more than sixty years it has been known that Mycobacterium tuberculosis was readily inhibited when growing in cultures, and a large number of substances have been found which have the property of inhibiting the growth of this organism, even in extremely high dilutions.[1] Until 1940 [2] a substance was not found which was capable of actually arresting experimental tuberculosis in the highly susceptible guinea pig.

The development of methods [3] which were adequate to assay the therapeutic potentialities of antibacterial drugs against experimental tuberculosis has made possible an extensive program of research which has steadily progressed toward attainment of a practical clinical goal. These methods led to the recognition of the sulfone series of synthetic drugs (sodium p,p′-diaminodiphenylsulfone-N,N′didextrose sulfonate, Promin; disodium formaldehyde sulfoxylate, Diasone; 4,2′-diaminodiphenyl-5′-thiazolesulfone, Promizole; 4,4′-diaminodiphenylsulfone and others) which were highly effective in treatment of tuberculosis in experimentally infected animals, but the clinical use of which was not feasible.[4] When these methods of assay were applied to streptomycin, soon after it was developed by Schatz, Bugie and Waksman,[5] its superior therapeutic potentialities were recognized promptly.[6]

We and our associates have been utilizing streptomycin clinically for approximately two years [7] and have treated 100 patients who had various types of tuberculous infection during this period.[8] Several of the patients had tuberculosis of more than one type or at more than one site (see the accompanying table). Streptomycin recently has been made available commercially, and it now appears advisable to record our observations in a widely distributed medical journal. In this paper we shall place emphasis on those types of tuberculosis which are usually treated by physicians and surgeons who do not limit their practice to phthisis.

The clinical use of streptomycin appears to be based on sound laboratory investigation. Observations on guinea pigs [6b] and on mice infected [9] with lethal doses of tubercle bacilli have shown that streptomycin may bring the disease to a state of arrest, even when severe experimental conditions were imposed. Our more recent observations have yielded even more impressive evidence of the striking antibacterial activity of streptomycin in vivo; resolution, fibrosis or calcification of lesions has occurred in all animals and apparent eradication of the infection in at least 30 per cent of the animals. Previously positive reactions to tuberculin tests have been reversed to negative reactions in those animals from whose organs Myco. tuberculosis could not be recovered by the most sensitive bacteriologic methods.

Tuberculosis Treated with Streptomycin: Summary of One Hundred Cases *

Type of Case	Number
Miliary tuberculosis and tuberculous meningitis	12
Nonsurgical pulmonary tuberculosis of adults	32
Ulcerating tuberculous lesions of respiratory tract	7
Tuberculous empyema	7
Tuberculous fistulas	15
Tuberculosis of the genitourinary tract	15
Tuberculosis of bones and joints	5
Surgical pulmonary tuberculosis of adults	7
Miscellaneous types of tuberculosis	11

* Eleven patients had tuberculosis of more than one type or location.

Streptomycin possesses the pharmacologic properties required of a substance to be used in the treatment of a chronic disease,[10] and recent accomplishments of the manufacturers have resulted in more purified and accordingly less toxic preparations than were formerly available. The drug is expensive to produce and difficult to procure in a quantity adequate for the treatment of tuberculosis. The entire output is now allocated by regulations of the Civilian Production Administration, for which Dr. E. O. Haenni is the director of the Drug Section of the Chemicals Division.

MILIARY TUBERCULOSIS AND TUBERCULOUS MENINGITIS

Twelve patients who had generalized hematogenous tuberculosis have been treated with streptomycin. Nine of these presented clinical evidence of meningitis, 2 had focal cerebral lesions of tuberculosis which were demonstrated at necropsy, and 1 had miliary tuberculosis without evidence of involvement of the central nervous system. Six of these 12 patients have died, and observations at necropsy in 5 instances have been

recorded.[11] Five patients who are still living have been observed for periods ranging from two to ten months following the clinical diagnosis. In the remaining case, treatment has been under way for one month only.

Of greatest interest are the 5 surviving patients observed for from two to ten months whose previously progressive disease has been suppressed at least temporarily by streptomycin therapy. One patient who had miliary tuberculosis without meningitis has shown pronounced improvement, both clinically and roentgenographically, after two months of treatment. The other 4 had well developed tuberculous meningitis which gave all the cardinal evidences of this disease, including the usual symptoms (fever, stupor, headache and nuchal rigidity) and the usual abnormalities of the cerebrospinal fluid, which contained demonstrable Myco. tuberculosis. The symptomatic response of these 4 patients to treatment with streptomycin has been sufficiently consistent and prompt to be unmistakable, and the subsequent clinical course has been unlike anything previously observed in this disease in our experience. Symptomatic improvement has usually been observed within one or two weeks after administration of streptomycin was begun; fever has declined within two or three weeks, and the temperature has become normal within four to eight weeks after the initiation of treatment. A return of a sense of well-being and the disappearance of stupor, headache and nuchal rigidity have been associated manifestations. The condition of the cerebrospinal fluid has improved slowly, and some abnormalities have persisted in all patients. Change in the spinal fluid to nearly normal has occurred in 2 patients only. It has been impossible to demonstrate Myco. tuberculosis in the cerebrospinal fluid after several weeks of treatment of these surviving patients. The fact that the cell count or the protein content has remained high or the sugar content of the cerebrospinal fluid has remained low has been interpreted as evidence of possible persistent infection in these patients whose tuberculous meningitis has improved, even though the organisms can no longer be demonstrated by inoculation of guinea pigs or culture. Treatment of 3 patients has been discontinued after the completion of a six months' course of therapy. Two of these patients have remained well for two and three months respectively. Reactivation of the disease of the other patient occurred one month after treatment was stopped; therefore, treatment was resumed. This patient is still alive more than three months after such reactivation and ten months after admission, but actual recovery appears improbable. The life of these patients undoubtedly has been prolonged for at least several months, and the distressing symptoms of tuberculous meningitis have been relieved; but much more time must elapse before any of these patients will be classified as cured.

Residual neurologic disturbances are present in 3 of the 4 patients with arrested tuberculous meningitis. One patient is blind, and we believe that the blindness was caused by tuberculous retrobulbar neuritis. One patient is deaf, and there is a question whether the deafness is due to the streptomycin. The third patient has profound disturbances of cerebellar function. The remaining patient is clinically well, ambulatory and free of all symptoms but is still receiving treatment five months after admission, with severe symptoms of early tuberculous meningitis.

One case of tuberculous meningitis arrested by treatment with streptomycin has been reported,[12] and we know of at least 6 other similar cases which have been reported to us by personal communication from various institutions.

The treatment of 4 patients has consisted of the intrathecal administration, by lumbar or cisternal puncture, of 100 to 200 mg. of streptomycin every twenty-four to forty-eight hours for two to six weeks. In addition, these patients received 2 to 3 Gm. of the substance daily by intramuscular injection, and this regimen has been continued for six months in the treatment of those who have been under observation for this long time. None of the patients who died had received intrathecal therapy, and none of those who received intrathecal therapy have died thus far. The clinical histories and observations at necropsy in those patients who died are discussed in another publication.[11]

In tuberculous meningitis maximal doses of streptomycin should be given both parenterally and intrathecally for prolonged periods. Frequently such treatment produces temporary clinical improvement which will persist for at least several weeks or months.

For miliary tuberculosis, early diagnosis and persistent treatment with maximal tolerated doses given parenterally should be undertaken. Clinical, roentgenographic and histopathologic evidences of healing trends have been observed, but actual cure has not yet been witnessed in our experience.

NONSURGICAL PULMONARY TUBERCULOSIS OF ADULTS

A total of 32 patients who have had pulmonary tuberculosis have been treated by us with streptomycin since December 1944. Patients with active, usually progressive cases of pulmonary tuberculosis in which we and our clinical associates[13] were of the opinion that rapid spontaneous improvement was unlikely to occur were selected for treatment with streptomycin. Cases in which nonspecific therapeutic measures or collapse therapy might contribute to the recovery of the patient were excluded from the series. Furthermore, cases in which surgical operation was employed were not included.

Of the 32 patients on whom operation was not performed, the pulmonary tuberculosis had reached a far advanced stage of development in 21, was moderately advanced in 9 and was minimal in 2 before treatment with streptomycin was begun. Constitutional symptoms such as fever, cough and loss of weight were moderate to severe in 27 patients. After treatment for from two to six months with 1 to 3 Gm. of the drug a day, definite roentgenographic improvement was observed in 25 patients, despite the unfavorable trends observed prior to treatment. Evidence that pulmonary cavities had closed was observed in 12 patients, apparently as a result of treatment; thick walled cavities persisted in 6 patients despite treatment, and in the rest cavitation was not demonstrable. Myco. tuberculosis disappeared from the sputum of 13 patients; in each of these instances this fact was proved either by culture or by inoculation of guinea pigs with aspirated gastric contents.

[12] Cooke, R. E.; Dunphy, D. L., and Blake, F. G.: Streptomycin in Tuberculous Meningitis: A Report of Its Use in a One-Year-Old Infant, Yale J. Biol. & Med. **18**: 221-226 (Jan.) 1946.

[13] Drs. H. J. Moersch, O. T. Clagett, H. G. Wood, H. W. Schmidt, A. M. Olsen and D. T. Carr of the Mayo Clinic, Dr. Magnus Petersen of the Rochester State Hospital and Dr. H. A. Burns of the Division of Public Institutions of the State of Minnesota have cooperated in the care of these patients.

Myco. tuberculosis continued to be found in the sputum of 15 patients with far advanced tuberculosis despite prolonged treatment, and in the remaining 4 patients the organisms were never demonstrated in the sputum, although the diagnosis of tuberculosis was undoubtedly correct.

Lesions of pulmonary tuberculosis were not observed to progress roentgenographically during treatment with streptomycin even in those cases which terminated fatally, with the exception of 1 instance mentioned hereafter of recurrent tuberculosis due to a drug-resistant strain of Myco. tuberculosis. In 7 cases the disease was classified as unimproved. Without exception these patients had far advanced lesions of long standing, thick-walled cavities and fibrocaseous lesions, which probably would not respond to any antibacterial therapy. Some of these 7 patients were subjectively improved, but this change frequently could be attributed to improvement in morale incident to alteration of treatment.

Reactivation of the disease attending discontinuation of treatment with streptomycin has been observed in 6 instances. Two of the patients promptly improved again when treatment was resumed, 1 failed to improve when a second course of treatment was given, and the remaining 3 did not receive further treatment with streptomycin. It appeared that the persistence of the organism in the sputum, uncollapsed cavities, emaciation and low natural resistance predisposed the patients to a recurrence of the disease after the discontinuation of treatment.

Five patients of this series who had pulmonary tuberculosis have died. Two received streptomycin until the end, and the other 3 did not have treatment during their last few months. Each of these patients had terminal, far advanced disease with involvement of the greater part of both lungs and was in an advanced stage of cachexia when treatment with streptomycin was instituted. There was temporary improvement for a few weeks in 2 of these patients, and in 2 the disease did not advance. The remaining case was of unusual interest because well defined improvement in the patient had occurred during a six months' course of treatment; reactivation of the disease took place four months later, and a streptomycin-resistant strain of Myco. tuberculosis was isolated. Despite a second course of treatment under these conditions, the disease followed a rapidly progressive course, due perhaps to an acquired resistance to streptomycin on the part of the infecting organisms.

In the selection of patients with pulmonary tuberculosis for treatment with streptomycin, preference should be given to those patients with progressive disease who cannot be treated effectively by conventional methods. Priority also should be given to those patients whose disease appears to be of such a character that it might be brought under permanent control with a few months of suppressive treatment with or without surgical intervention.

ULCERATING TUBERCULOUS LESIONS OF THE RESPIRATORY TRACT

Ulcerating tuberculous lesions of the respiratory passages, including the larynx,[14] hypopharynx, trachea and large bronchi, have been treated in 7 cases. Observations are still incomplete in 2 cases, but in the remaining 5 prompt improvement of the patients was observed and recurrences have not been noted, although treatment has been completed for a year or more in 4 cases.

TUBERCULOUS EMPYEMA

Seven patients with tuberculous empyema of long standing have been treated with streptomycin. Four of these were given the preparation intrapleurally only, and improvement was not observed beyond that which might be anticipated had lavage alone been employed. Three patients received treatment by both intrapleural and intramuscular routes, and only 1 of these improved unmistakably. In 1942, this 1 patient had required open thoracotomy with resection of three ribs and intercostal muscles for drainage of tuberculous empyema with mixed infection and large bronchopleural fistula. It was possible to apply the streptomycin to the pleural surfaces several times a day by means of an atomizer, and, in addition, large doses were given intramuscularly. The bronchopleural fistula closed promptly, and Myco. tuberculosis disappeared from the empyemic cavity after three months of treatment. This patient had been under observation for four years previously, and improvement had not occurred despite persistent treatment of several types.

It is surprising that the antibacterial effects of streptomycin are not more clearly shown in the treatment of tuberculous empyema, but this may be due to the fact that the pus of tuberculous empyema is usually acid in reaction, while streptomycin is much more active in neutral or alkaline solutions. Also, it should be recalled that tuberculous empyema is a granulomatous process and not a simple growth of bacilli in the empyemic fluid.

TUBERCULOUS FISTULAS

Fifteen patients with cutaneous fistulas from which purulent material containing Myco. tuberculosis drained have been treated with streptomycin. One of these had multiple lesions which involved the supraclavicular lymph nodes, the inguinal lymph nodes and the chest wall. Lesions were limited to the cervical and axillary lymph nodes in 6 patients, to the thoracic wall in 2, to the abdominal wall in 1 and to the scrotum in 2. Two patients had tuberculosis of the bones of the wrist, with draining sinuses, and 1 had a tuberculous infection of a wound in the scalp following craniotomy for tuberculoma of the brain. In the patient with tuberculoma of the brain, treatment with streptomycin was continued for six weeks only. Temporary neurologic improvement resulted, but this may have been due to the decompression operation. This patient died elsewhere six months later.

In each of the 15 patients a response to therapy has been observed within four to six weeks; this response was evidenced by the cessation of purulent drainage. If treatment was suspended at this stage of improvement, a tendency toward prompt spontaneous reactivation of the process was observed. When treatment was continued for several weeks after complete superficial healing had been accomplished, an indefinitely long remission of the disease has usually been observed. In 10 of the 15 patients the fistulas have healed and have remained closed for periods of four to twelve months, in 3 patients recurrent fistulas remain, and in 2 patients recent healing has occurred, but treatment is still under way. In order to achieve complete and prolonged healing of such lesions the administration of 2 Gm. of streptomycin per day for at least three or four months is recommended as an average dosage.

---

[14] Figi, F. A.; Hinshaw, H. C., and Feldman, W. H.: Treatment of Tuberculosis of the Larynx with Streptomycin: Report of Case, Proc. Staff Meet., Mayo Clin. **21**: 127-130 (March 20) 1946.

Streptomycin has appeared to facilitate the healing of previously refractory tuberculous fistulous tracts, especially those due to tuberculosis of the chest wall and tuberculous lymphadenitis. Treatment should be continued for several weeks after purulent drainage ceases in order to reduce the possibility of recurrence.

TUBERCULOSIS OF THE GENITOURINARY TRACT

The experience of our group in treatment of tuberculosis of the genitourinary tract has been recorded elsewhere,[15] and further observations on a total of 15 cases have confirmed the conclusion that streptomycin possesses some palliative value in the majority of cases of tuberculous cystitis and may bring the disease to a state of temporary arrest in a small minority of cases. Streptomycin is not curative of renal tuberculosis, in our opinion. More impressive symptomatic results might have been realized in cases of tuberculous cystitis had earlier cases been chosen in which there were less advanced fibrotic changes in the bladder wall.

In the types of cases chosen we have observed a decided tendency to recurrence of tuberculous bacilluria, even after the urine had been proved free of Myco. tuberculosis by the results of inoculation of guinea pigs. When the organisms reappear in the urine after prolonged treatment with streptomycin, they are likely to be resistant to the effects of the drug in vitro. Amelioration of symptoms, which has been observed in at least 50 per cent of the 15 cases, frequently has been prolonged. Two patients who were first treated more than eighteen months ago continue to experience considerable symptomatic relief, even though small numbers of Myco. tuberculosis occasionally appear in the urine.

Two of this group of 15 patients had fistulas of the scrotum from which pus containing bacilli related to tuberculous epididymitis drained. In each of the 2 these fistulas closed within a few weeks after the institution of treatment with streptomycin and have remained healed for six and ten months, respectively, after the discontinuation of treatment.

Patients with tuberculous cystitis are frequently improved at least temporarily by the use of streptomycin. The actual arrest of renal tuberculosis has rarely, if ever, been achieved by this treatment. Streptomycin therapy, therefore, cannot be regarded as a substitute for the surgical treatment of unilateral renal tuberculosis at this time.

TUBERCULOSIS OF BONES AND JOINTS

Tuberculosis of bones and joints has been treated in 5 cases. Observations are incomplete in 1 case because the patient is still under treatment. Apparent response of the patients to treatment has been noted, however, in the remaining 4 cases, which will be reported in collaboration with our associates in orthopedic surgery.

SURGICAL PULMONARY TUBERCULOSIS OF ADULTS

Streptomycin was combined with radical surgical measures in treatment of 7 patients who had pulmonary tuberculosis. The streptomycin was given both preoperatively and postoperatively; in some cases the main reason for postoperative administration of streptomycin was to combat postoperative tuberculous complications. It is believed that the drug contributed substantially to the recovery of the patients, and a more detailed report of the cases will be published with colleagues of ours who perform thoracic surgery.

MISCELLANEOUS TYPES OF TUBERCULOSIS

Because of the pronounced tendency to spontaneous healing of primary tuberculosis, it is difficult to evaluate the results of treatment in the 2 cases of primary pulmonary tuberculosis of childhood which were included in this series. One of these cases has already been mentioned, and enumerated, as an instance of tuberculous meningitis.

Tuberculosis of the peritoneum has been treated in 3 cases with apparently good results. Recent surgical treatment may have contributed to the recovery in 1 case. Tuberculous pericarditis also was present in 1 of these cases of peritoneal involvement and persistent postoperative tuberculous infection of the wound was treated with streptomycin; drainage ceased and systemic improvement occurred.

Three patients who had lupus vulgaris and 1 who had sarcoidosis were treated with streptomycin. Good results were obtained in 1 patient with lupus, and questionable improvement occurred in the remainder. These cases will be reported in more detail by our associates in dermatology.[16]

Three patients are being treated for ocular tuberculosis by our associates in ophthalmology, and results are not as yet fully evaluated.

DOSAGE, METHODS OF ADMINISTRATION AND TOXICITY OF STREPTOMYCIN

The dosage of streptomycin which we recommend at this time for treatment of tuberculosis of adults is from 1 to 3 Gm. per twenty-four hours. This quantity is divided into four or six doses, one of which is administered every four or six hours by deep subcutaneous or intramuscular injection. The solution for parenteral administration may contain from 100 to 250 mg. of streptomycin per cubic centimeter. Sterile water is the diluent of choice. Solutions containing 25 to 100 mg. per cubic centimeter may be employed topically, intrabronchially or in an aerosol spray. In the treatment of tuberculous meningitis, intrathecal injections of from 100 to 200 mg. of streptomycin dissolved in 1 to 5 cc. of cerebrospinal fluid or isotonic solution of sodium chloride are given every twenty-four to forty-eight hours by lumbar or cisternal puncture.

Treatment of ulcerating tuberculous lesions of the hypopharynx, larynx, trachea and bronchi may include both parenteral and aerosol treatment with streptomycin. The aerosol has been administered by means of a nebulizer in a manner similar to that employed in bronchiectasis.[17] For this, 20 cc. of isotonic solution of sodium chloride which contains 0.5 Gm. of streptomycin is used; 2 cc. is nebulized into the mouth each hour for ten hours of the day.

Treatment with streptomycin for prolonged periods, as is required for tuberculosis, has produced reactions

Streptomycin has appeared to facilitate the healing of previously refractory tuberculous fistulous tracts, especially those due to tuberculosis of the chest wall and tuberculous lymphadenitis. Treatment should be continued for several weeks after purulent drainage ceases in order to reduce the possibility of recurrence.

TUBERCULOSIS OF THE GENITOURINARY TRACT

The experience of our group in treatment of tuberculosis of the genitourinary tract has been recorded elsewhere,[15] and further observations on a total of 15 cases have confirmed the conclusion that streptomycin possesses some palliative value in the majority of cases of tuberculous cystitis and may bring the disease to a state of temporary arrest in a small minority of cases. Streptomycin is not curative of renal tuberculosis, in our opinion. More impressive symptomatic results might have been realized in cases of tuberculous cystitis had earlier cases been chosen in which there were less advanced fibrotic changes in the bladder wall.

In the types of cases chosen we have observed a decided tendency to recurrence of tuberculous bacilluria, even after the urine had been proved free of Myco. tuberculosis by the results of inoculation of guinea pigs. When the organisms reappear in the urine after prolonged treatment with streptomycin, they are likely to be resistant to the effects of the drug in vitro. Amelioration of symptoms, which has been observed in at least 50 per cent of the 15 cases, frequently has been prolonged. Two patients who were first treated more than eighteen months ago continue to experience considerable symptomatic relief, even though small numbers of Myco. tuberculosis occasionally appear in the urine.

Two of this group of 15 patients had fistulas of the scrotum from which pus containing bacilli related to tuberculous epididymitis drained. In each of the 2 these fistulas closed within a few weeks after the institution of treatment with streptomycin and have remained healed for six and ten months, respectively, after the discontinuation of treatment.

Patients with tuberculous cystitis are frequently improved at least temporarily by the use of streptomycin. The actual arrest of renal tuberculosis has rarely, if ever, been achieved by this treatment. Streptomycin therapy, therefore, cannot be regarded as a substitute for the surgical treatment of unilateral renal tuberculosis at this time.

TUBERCULOSIS OF BONES AND JOINTS

Tuberculosis of bones and joints has been treated in 5 cases. Observations are incomplete in 1 case because the patient is still under treatment. Apparent response of the patients to treatment has been noted, however, in the remaining 4 cases, which will be reported in collaboration with our associates in orthopedic surgery.

SURGICAL PULMONARY TUBERCULOSIS OF ADULTS

Streptomycin was combined with radical surgical measures in treatment of 7 patients who had pulmonary tuberculosis. The streptomycin was given both preoperatively and postoperatively; in some cases the main reason for postoperative administration of streptomycin was to combat postoperative tuberculous complications. It is believed that the drug contributed substantially to the recovery of the patients, and a more detailed report of the cases will be published with colleagues of ours who perform thoracic surgery.

MISCELLANEOUS TYPES OF TUBERCULOSIS

Because of the pronounced tendency to spontaneous healing of primary tuberculosis, it is difficult to evaluate the results of treatment in the 2 cases of primary pulmonary tuberculosis of childhood which were included in this series. One of these cases has already been mentioned, and enumerated, as an instance of tuberculous meningitis.

Tuberculosis of the peritoneum has been treated in 3 cases with apparently good results. Recent surgical treatment may have contributed to the recovery in 1 case. Tuberculous pericarditis also was present in 1 of these cases of peritoneal involvement and persistent postoperative tuberculous infection of the wound was treated with streptomycin; drainage ceased and systemic improvement occurred.

Three patients who had lupus vulgaris and 1 who had sarcoidosis were treated with streptomycin. Good results were obtained in 1 patient with lupus, and questionable improvement occurred in the remainder. These cases will be reported in more detail by our associates in dermatology.[16]

Three patients are being treated for ocular tuberculosis by our associates in ophthalmology, and results are not as yet fully evaluated.

DOSAGE, METHODS OF ADMINISTRATION AND TOXICITY OF STREPTOMYCIN

The dosage of streptomycin which we recommend at this time for treatment of tuberculosis of adults is from 1 to 3 Gm. per twenty-four hours. This quantity is divided into four or six doses, one of which is administered every four or six hours by deep subcutaneous or intramuscular injection. The solution for parenteral administration may contain from 100 to 250 mg. of streptomycin per cubic centimeter. Sterile water is the diluent of choice. Solutions containing 25 to 100 mg. per cubic centimeter may be employed topically, intrabronchially or in an aerosol spray. In the treatment of tuberculous meningitis, intrathecal injections of from 100 to 200 mg. of streptomycin dissolved in 1 to 5 cc. of cerebrospinal fluid or isotonic solution of sodium chloride are given every twenty-four to forty-eight hours by lumbar or cisternal puncture.

Treatment of ulcerating tuberculous lesions of the hypopharynx, larynx, trachea and bronchi may include both parenteral and aerosol treatment with streptomycin. The aerosol has been administered by means of a nebulizer in a manner similar to that employed in bronchiectasis.[17] For this, 20 cc. of isotonic solution of sodium chloride which contains 0.5 Gm. of streptomycin is used; 2 cc. is nebulized into the mouth each hour for ten hours of the day.

Treatment with streptomycin for prolonged periods, as is required for tuberculosis, has produced reactions which, although incompletely understood, must be anticipated. These are of sufficient severity that treatment with streptomycin frequently should be denied to patients for whom the prognosis from conventional therapy is good. These reactions, however, are sufficiently mild to be disregarded in cases of progressive tuberculosis which is not amenable to other forms of treatment. The most frequent and uncomfortable reaction observed in our experience is disturbance of equilibrium. Effective compensation for this disturbance may occur, with eventual disappearance of symptoms. However, evidence of permanent neurologic abnormality frequently persists in the form of a diminished response to caloric stimulation of the vestibular apparatus.[18] We do not recommend that treatment be discontinued when disturbance of equilibrium is observed, for experience has shown that compensation occurs even though treatment is prolonged.

[17] Olsen, A. M.: Nebulized Penicillin: Preliminary Report of Its Role in the Management of Surgical Bronchiectasis, Proc. Staff Meet., Mayo Clin. **20**: 184-194 (June 13) 1945.

Other toxic manifestations previously described may be due to impurities in the streptomycin. Irritation at the site of injection is widely variable and inversely proportional to the purity of the product. Renal damage is not likely to occur, but until clinical studies on the prolonged use of purified preparations of streptomycin have been completed, it is recommended that renal function be observed closely. Histamine-like reactions are definitely caused by impurities and do not occur with preparations now available.

LIMITATIONS OF STREPTOMYCIN IN TUBERCULOSIS

It is wise to recognize as clearly as possible the limitations which are imposed on the treatment of clinical tuberculosis by chemotherapeutic and antibiotic agents and, especially, to emphasize the limitations and shortcomings of streptomycin. Unfortunately, tuberculosis in human beings pursues an insidious course; often it does not produce symptoms until irreversible destructive changes have been wrought in the tissues. The mechanical handicaps to healing brought about by the destructive and reparative forces involved frequently require surgical correction, and many forms of localized tuberculous infection have become primarily surgical diseases. It appears illogical to anticipate that the use of any antibacterial preparation could replace the surgical treatment of such lesions. It is more logical to anticipate that a bacteriostatic substance would widen the indications for surgical treatment if it will suppress the unfortunate trend toward rekindling of the infection produced by surgical manipulation of tuberculous tissues. Actual healing in tuberculosis must be accomplished by the slow processes of resorption, fibrosis and calcification, and the role of an antibacterial drug is that of blocking the paths for extension of the disease while these healing forces are operating.

Problems incident to the acquisition by Myco. tuberculosis of resistance to the effects of streptomycin loom large at this time. It appears that the metabolic block in bacterial metabolism produced by streptomycin is more easily overcome by all organisms susceptible to the antibacterial effects of this substance than is the block produced by other known antibacterial agents on organisms susceptible to them. This fact accentuates the importance of devising alternative methods of attack against the organism, to be brought into play when the effectiveness of streptomycin has been exhausted.

Experimental[19] and clinical evidence indicates that there is some limitation as to the duration of therapeutic effect in those instances in which the bacillus develops an acquired resistance to streptomycin. The duration of action of the drug is variable but is sufficiently prolonged to accomplish a favorable result in many clinical situations.

SUMMARY

Streptomycin is an antibacterial agent which possesses the unique ability to inhibit the growth of Mycobacterium tuberculosis in vivo, both experimentally and clinically. The manifestations of tuberculosis may be suppressed both in experimental animals and in man, with at least temporary retardation of the pathologic processes as judged by objective criteria.

In many instances streptomycin appears to suppress tuberculosis rather than to eradicate it, being apparently bacteriostatic rather than completely bactericidal in the concentrations which can be obtained in the tissues.

Streptomycin is recommended for more extensive trial in treatment of many forms of pulmonary and extrapulmonary tuberculosis because of definitely and consistently encouraging results attendant on its use in a series of 100 cases in the past two years.

Treatment of tuberculosis requires large doses of streptomycin (1 to 3 Gm. a day) for prolonged periods and should not be undertaken unless adequate amounts are likely to be available to complete a course of at least two to four months' duration (total requirements up to 360 Gm.).

Toxic manifestations should be anticipated in a majority of patients in whom such prolonged treatment is carried out. Disturbance of equilibrium is especially likely to occur and often persists for at least several weeks after the discontinuation of streptomycin therapy.

Treatment with this antibiotic should be postponed or denied to those tuberculous patients who are making satisfactory progress and who are likely to achieve the arrest of their disease as a result of conventional therapeutic methods. Streptomycin is not to be regarded as a substitute for other and proved effective forms of treatment of tuberculosis.

Letters of Benjamin Rush.—Toward the end of May 1943 there opened at the best known auction house in New York a remarkable sale of American historical manuscripts. This was the sale of the Alexander Biddle Papers. . . . Alexander Biddle had married Julia Wilmer Rush, who brought with her a large segment of the papers of her grandfather Dr. Benjamin Rush. Some 400 lots in the sale consisted of letters to Rush from such friends as John Abigail and John Nathanael Greene, John Jay, Thomas Jefferson, Thaddeus Kosciuszko, Charles Lee, James Madison, James Monroe, Thomas Paine, David Rittenhouse, Anthony Wayne and John Witherspoon. The letters of all those named have always, for good reasons, been eagerly sought by collectors and institutions. The first among the approximately 125 Rush letters in the sale went for $100 or more apiece, some later ones went for $200 or more, and two of them—I am sorry to say they describe quarrels with other physicians—sold for over $300. After some study of the matter I am prepared to say they were worth the prices paid.—Butterfield, L. H.: Benjamin Rush: A Physician As Seen In His Letters, *Bull. Inst. Hist. Med.*, July 1946.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 701)

(Note.—*Following is the fourth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of The Journal. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in The Journal. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—Ed.)

CHAPTER 4. *The Principles of Medical Ethics*

Among the resolutions introduced in the National Medical Convention which assembled in New York in May 1846 was one which was to set a pattern of ideals for all the years that have followed. It read:

> that it is expedient that the medical profession in the United States should be governed by the same code of medical ethics, and that a committee of seven be appointed to report a code for that purpose at a meeting to be held in Philadelphia on the first Wednesday of May 1847.

The committee included Drs. John Bell, Isaac Hays and G. Emerson, Philadelphia; W. W. Morris, Dover, Del.; T. C. Dunn, Newport, R. I.; A. Clark, New York, and R. D. Arnold, Savannah, Ga. This committee presented its report on June 5, 1847 at Philadelphia.

In presenting the report Dr. Isaac Hays stated that justice required that some explanatory remarks should accompany it. The committee had examined a great number of codes of ethics adopted by different societies in the United States and found that they were all based on that of Dr. Thomas Percival and that, moreover, the phrases of this writer were preserved to a considerable extent in all of them. "Believing that language which had been so often examined and adopted must possess the greatest of merits for such a document as the present, clearness and precision, and having no ambition for the honours of authorship, the Committee which prepared this code have followed a similar course and have carefully preserved the words of Percival wherever they convey the precepts it is wished to inculcate. A few of the sections are in the words of the late Dr. Rush, and one or two sentences are from other writers." The committee said, however, that wherever it was thought that the language could be made more explicit by changing a word or even a part of a sentence, this was unhesitatingly done.

Dr. John Bell was a Philadelphia surgeon, graduated by the University of Pennsylvania in 1817. He had done good work as a writer and editor and had been associated with the production of a considerable number of books. He had also edited "Stokes' Lectures on the Theory and Practice of Physics" and Andrew Combe's "Treatise on Children." It is generally conceded that most of the work in the preparation of these principles of ethics had been done by Isaac Hays, editor of the *American Journal of the Medical Sciences* from 1827 to 1879.

Thomas Percival, from whom admittedly the committee drew extensively in preparing the first draft of the principles of ethics, was a graduate of Leyden in 1765 and was made a Fellow of the Royal Society of England in 1765 when he was 25 years old. In 1767, when he was 27 years old, Thomas Percival published a book of philosophic essays and commentaries on medical life. He conducted an extensive correspondence with John Hunter and William Withering, the latter the discoverer of the use of digitalis, and with Heberden, for whom the famous nodes are named. He was associated with Charles White, who unquestionably knew about the infectiousness of puerperal fever and who wrote important works on the subject before Semmelweis and Oliver Wendell Holmes. Thomas Percival gave much thought to the future of the medical profession. An argument started in the hospital in which he worked. This no doubt led to the codification of the principles which were the first formal code of ethics submitted to the English medical profession. In 1793 Percival was asked by the group associated with the Manchester Infirmary to draw up a series of ethical principles as a guide in the conduct of the hospital and of the infirmary. He worked three years, then drew a first draft which he circulated among his friends, including Charles White, Heberden, John Hunter and William Withering. He sent a copy also to Erasmus Darwin. All sent him their comments. Then he revised the manuscript and finally published it in 1803.

In 1823 the New York State Medical Society adopted a series of principles of ethics which were almost wholly similar to the code prepared by Thomas Percival. In 1832 the Baltimore Medical Society took Percival's series and adopted them for that society. When Isaac Hays presented the report of his committee to the convention of 1847, he too, as has already been noted, decided that little improvement could be made on the principles as set forth by Thomas Percival.

In the work "American Medical Biographies," by Howard A. Kelly and Walter L. Burrage, it is said that the name of Isaac Hays is always associated with that which is well written and worth reading in American medical literature. After graduation from the University of Pennsylvania in 1816 his father put Isaac Hays into his counting house, but one year of banking proved to be enough. Hays took up the study of medicine under Dr. Nathaniel Chapman, among the first of the presidents of the American Medical Association. In 1820 Hays took his M.D. at the University of Pennsylvania with a thesis on the subject of sympathy. Hays gained celebrity in surgery of the eye; he edited several books on diseases of the eye, physics and ornithology, and cooperated in the preparation of a dictionary of medical terms. He translated several important works of medicine from French into English and he began an American Cyclopedia of Practical Medicine and Surgery but got only as far as "A to Azygos." In 1833 he had published a work entitled

"Descriptions of the Inferior Maxillary Bones of the Mastodons" and he recorded the first case of astigmatism recorded in America.

In presenting the Code of Medical Ethics to the convention, a statement was made by Dr. John Bell in which he pointed out that medical ethics comprised not only the duties but also the rights of a physician. "As it is the duty of a physician to advise, so has he a right to be attentively and respectfully listened to." His introductory statement, after emphasizing the dignity of the medical profession, calls on the physician to give of his utmost for the advancement of the public health and the sustaining of the law. He recognizes the obligation on the physician "to bear emphatic testimony against quackery in all its forms." Even as early as 1847 he recognized the dangers of insanitary food and the purveying of nostrums. He did not hesitate to condemn members of other professions, and especially ministers of the gospel, for giving "their countenance and at times direct patronage to medical empirics both by their use of nostrums and by their certificates in favor of the absurd pretentions of these impostors." He condemned also the apothecaries who lend themselves to the sale and distribution of quack medicines and nostrums. And the final portion of his address is a plea to maintain the standards of the profession by unceasing vigilance so as to prevent the introduction of those who have not been prepared by a suitable preparatory moral and intellectual training.

In a volume called "Percival's Medical Ethics," Chauncey D. Leake has analyzed the growth and development of the "Principles of Medical Ethics of the American Medical Association." The criticism was made early that the committee headed by Bell and Hays had taken its code directly from the New York State code. However, as has already been pointed out, Isaac Hays stated clearly that the code had been derived from that of Percival and thus neatly reprimanded the New York and Baltimore societies, which adopted these codes without giving credit to Percival.

From time to time after 1848, circumstances developed which made necessary reconsiderations and modifications of the Principles of Ethics. In 1852 there was serious debate over the acceptance of homeopathic doctrines by some members of the medical profession. In 1882 delegates from the Medical Society of the State of New York presented a report which offered a simplified and brief system of medical ethics as a substitute for the national code. This was adopted. Then in June 1882, at the meeting of the American Medical Association in St. Paul, delegates from the Medical Society of the State of New York were refused admission. At that time Dr. Austin Flint wrote a commentary on the Code of Ethics in an endeavor to persuade the New York society to reenact the code of the American Medical Association. So fierce was this battle that a group was formed with the title "Society for the Prevention of the Reenactment in the State of New York of the Present Code of Ethics of the American Medical Association." The battle continued with pamphleteering, debate and discussion on both sides. At various meetings of the Medical Society of the State of New York the Code was voted in and voted out, and at one time a conservative group which found it impossible to reenact the national code in the original Medical Society of the State of New York withdrew and organized a rival New York State Medical Association.

Finally, in 1903 a special committee appointed by the American Medical Association made a report at the convention in New Orleans to which one of its members dissented. That member prepared what he considered to be a "suitable system of advisory precepts" in medical conduct. This was adopted as "The Principles of Ethics of the American Medical Association" and was considered to be much more satisfactory than the older code. Still further revisions were made in 1912.

A resolution passed by the House of Delegates of the American Medical Association in San Francisco in 1946 has called on the Judicial Council of the American Medical Association to consider again a rewriting and rephrasing of "The Principles of Medical Ethics."

The chief criticism made by Chauncey D. Leake in his consideration of the subject is the one which has been made frequently, namely that "The Principles of Medical Ethics" do not clearly differentiate actual principles of ethics from the rules of conduct and etiquette of the profession. Indeed, one rather wise commentator in the midst of the battle that was waged in New York, Dr. D. B. St. John Roosa, suggested that the only ethical offenses for which the medical profession should claim and promise to exercise discipline are "those comprehended under the commission of acts unworthy a physician and a gentleman."

The "Principles of Ethics" that now prevail emphasize first the duties of the physician to his patient. These duties include service as an ideal, patience and delicacy as highly desirable qualifications and full assumption of responsibility once a case has been undertaken. The "Principles of Ethics" emphasize that the physician is free to choose whom he will serve but point out that he should respond to any request for assistance in emergencies or whenever temperate public opinion expects the service.

The physician is told that he must be an honorable man and a gentleman and that he must conform to a high standard of morals and uphold the dignity of his profession. The solicitation of patients by an individual physician is considered unprofessional, but it is recognized that a man may conform to the customs of the community in which he lives.

Medicine has for years depended for its success on the personal relationship between physician and patient. Every article in the principle of ethics is planned to emphasize this relationship. "A pleased patient," as the "Principles of Ethics" repeatedly state, "is the best type of medical advertisement." From the very first the "Principles of Ethics" have sought to protect an uninformed public against the claims of the quack and the pretender. "It is unprofessional to promise radical cures; to boast of cures and secret methods of treatment and remedies; to exhibit certificates of skill or of success in the treatment of disease; or to employ any methods to gain the attention of the public for the purpose of obtaining patients."

Again the "Principles of Ethics" recognized the importance of having adequate consultation whenever a physician is in doubt as to what is best for his patient. "In serious illness, especially in doubtful or difficult conditions, the physician should request consultations." And, the principles continue, "In every consultation the benefit to be derived by the patient is of first importance." The "Principles of Ethics" recognize that medical diagnosis is usually paid for insufficiently in comparison with the rewards of surgical technic. "The patient should be made to realize," say the "Principles of Ethics," "that a proper fee should be paid the family physician for the service he renders in determining the surgical or medical treatment suited to the condition, and in advising concerning those best qualified to render any special service that may be required by the patient."

THE DOCTOR AND THE PUBLIC

The third phase of the principles of ethics is again a recognition of the duty of the physician to the public. He is asked to remember that he is a citizen and to aid in enforcing laws and in giving advice concerning public health. During an epidemic he must continue his labors for the alleviation of the suffering without regard to the risk of his own health or life or to financial return. He is asked to warn the public against the devices practiced and the false pretensions made by charlatans, and he is told finally that these principles do not cover all the obligations which he may have but are wholly a guide which will supplement the ordinary conduct of a gentleman and the practice of the Golden Rule. The last sentence reads "Finally, these principles are primarily for the good of the public, and their enforcement should be conducted in such a manner as shall deserve and receive the endorsement of the community."

Clinical Notes, Suggestions and New Instruments

APPARENT SENSITIVITY TO AMIGEN

HAROLD J. HARRIS, M.D.
ONSLOW A. GORDON, M.D.
ROBERT GRAY, M.D.
Westport, N. Y.
and
LYMAN G. BARTON, M.D.
Plattsburg, N. Y.

A girl aged 17 took approximately 125 grains (8.1 Gm.) of phenobarbital with suicidal intent on Aug. 15, 1946. Coma rapidly ensued. She had successfully fought off attempts at lavage. There was temporary response to dextrose given by the intravenous drip method, but a fatal outcome still seemed likely on the fourth day of coma. Dosages of picrotoxin and caffeine were of questionable value. The blood pressure ranged from 100 systolic and 60 diastolic to 120 systolic and 70 diastolic, the temperature from 101 to 103 F. and the pulse rate from 120 to 140 per minute. Complete blood counts were not especially informative.

The administration of amigen[1] 5 per cent in 5 per cent dextrose was begun by the slow intravenous drip method on the evening of the fourth day. By the time that approximately 100 cc. of the solution had been administered, a chill occurred. The intravenous drip medication was discontinued. The temperature rose rapidly to 105.8 F. and the pulse rate rose to 164 or higher. The application of cold wet packs and the use of ice water enemas were followed by a gradual decline of the temperature to 103 F., at which point these measures were discontinued. Shock ensued, with an irregular thready pulse and a steady fall of the blood pressure to 70 systolic and zero diastolic. At that point the pulse could not be felt.

Epinephrine hydrochloride given intramuscularly resulted in a temporary response, the heart action becoming audible and a thready irregular pulse at the rate of 160 per minute being reestablished. Additional amounts of epinephrine and caffeine and sodium benzoate did not give further response. The respirations were extremely shallow and gasping. The extremities were cold, blue and mottled. Nikethamide (Coramine, pyridine-*B*-carboxylic acid diethylamide) was administered intravenously in doses of 5.0 cc. each when a fatal termination seemed inevitable. By the time about 1.0 cc. of Nikethamide had been given, concomitantly with the initiation of intravenous drip of 10 per cent dextrose in distilled water, the respirations became deeper and less labored. Improvement in the pulse rate and blood pressure was rapid. Additional Nikethamide was given intramuscularly in doses of 5.0 cc. to 6.0 cc. at irregular intervals, whenever respirations became embarrassed.

From that time on improvement was steady. Partial return to consciousness followed in about forty-eight hours, and speech returned slowly, in typical fashion, with long intervals of semicomatose states.

Radiographs taken at the bedside showed increased density in areas roughly corresponding to the upper and lower lobes of the right lung. Breath sounds were slightly increased in pitch, but other physical signs of a pneumonic process were lacking. Penicillin, 25,000 units every three hours, had been given intramuscularly since the second day of the coma as a precaution against possible infection of the respiratory tract. It is probable that the growth of any pathogenic organisms was prevented by this measure. The temperature slowly defervesced. Subsequent to the patient's recovery from the collapse which followed the use of amigen, respirations were never suggestive of an infectious pneumonic process. Mucus had been coughed up or aspirated in profuse quantities from the onset of coma, at first blood-tinged, then frothy and finally purulent. It was felt that this bronchorrhea was the cause of the physical and radiographic observations. The term "bronchorrheic pneumonia" is proposed to distinguish this type, probably of common occurrence in barbiturate poisoning, from "aspiration" pneumonia, hypostatic pneumonia or infectious pneumonia, either lobar or bronchial.

This patient was known to have been sensitive to horse serum. A severe serum sickness had followed the administration of antistreptococcus serum for erysipelas at the age of 10 months. There was no other history of allergy.

SUMMARY

A 17 year old girl, suffering from the effects of a lethal dose of phenobarbital, collapsed following the institution of a slow intravenous drip of amigen. Death seemed inevitable. Nikethamide in large doses apparently was effective in stimulating the failing respiratory rate and can probably be credited with averting a fatal termination.

CONCLUSION

Amigen may give rise to serious foreign protein reactions.

INOCULATION TUBERCULOSIS

H. E. BASS, M.D.
New York

Inoculation tuberculosis, although infrequent, does occur.[1] A review of the literature indicates that a differentiation must be made between the true primary complex and reinfection tuberculosis. The occurrence of a tuberculous chancre and regional swelling of the lymph node is of great differential aid, especially when accompanied with a change from a negative to a positive tuberculin reaction.

The characteristics of the tuberculous chancre have been well described.[2] Stokes[3] reviewed the subject of primary inoculation tuberculosis of the skin. The following report of a case is considered to be of unusual interest because of the circumstances incident to the occurrence of a typical cutaneous chancre with regional tuberculous lymphadenitis.

REPORT OF CASE

The patient was a former army officer, white, aged 25, without any previous significant medical history. He had not knowingly been exposed to tuberculosis. On Jan. 15, 1945 he received multiple superficial wounds of the face, in part from shell fragments and in part from splinters of wood from the barn in Belgium in which he had taken shelter. He was hospitalized, and fragments of metal and wood were excised from his face. On February 12 he returned to duty, all areas apparently fully healed.

On February 16 he first observed a tender swelling "like a boil" just lateral to the external canthus of the right eye, at a point where a fragment of wood had been excised. At the same time he noted a tender swelling below the right mandible. He received treatment by hot packs, but the swelling over the face and in the neck increased.

He was hospitalized on Feb. 24, 1945. On admission he was febrile and nauseated. He received intravenous fluids and penicillin, with prompt disappearance of fever and nausea. Two diagnostic needle aspirations of the swelling near the right eye were performed, but records of the results are not available. Under treatment with hot compresses, the facial lesion broke down and formed an ulcer, which measured ½ inch (1.27 cm.) in diameter. The edges were elevated, and the base did not bleed when rubbed. The node in the right anterior cervical triangle was the size of a small egg, and two marble-sized nodes also were found just above the right clavicle. It was noted that the appearance of the ulcer suggested a malignant lesion.

On April 10, 1945 the ulcer and the large cervical lymph gland were excised under general anesthesia. Microscopic examination revealed caseofibroepithelioid and epithelioid giant cell tuberculosis, involving 90 per cent of the lymph node. Ziehl-Neelsen carbolfuchsin stain revealed acid-fast bacilli. Examination of the skin revealed epithelioid giant cell and caseo-epithelioid tuberculosis. Acid-fast bacilli were found in the section.

A tuberculin test revealed a 2 plus reaction to first strength purified protein derivative of tuberculin. Examination of the blood showed: red blood cells 4,700,000, hemoglobin 90 per cent, white blood cells 7,500, polymorphonuclears 66 per cent, lymphocytes 32 per cent, and eosinophils 2 per cent. The sedimentation rate was 17 mm. (Westergren). He received three treatments with roentgen ray to the lesions on his face and neck, each treatment consisting of 75 r. He also received a short course of ultraviolet therapy.

At a follow-up examination on Aug. 31, 1945 there were two pinhead-sized, slightly depressed brownish lesions which, in the opinion of the skin consultant, represented active tuberculosis. These lesions were present on the surface of the scar over the right zygomatic area. On the right side of the neck there was a moderately indurated scar, 1 inch (2.54 cm.) in length. Two pea-sized nodes were palpable just above the right clavicle. On Sept. 3, 1946 the scar over the right zygomatic area was completely healed. The scar in the neck had not changed since the previous examination. The glands on the right side of the neck were small and had not changed appreciably in size.

COMMENT

This case presents the unusual aspect of clinically primary tuberculosis of the skin following a war injury. It is noteworthy that clinical symptoms appeared approximately one month following the injury. It would have been of great interest to determine whether the Mycobacterium tuberculosis bacilli which were found in both ulcer and gland were of the bovine or human type, but unfortunately this was not done.

266 West End Avenue.

Council on Industrial Health

THE RECOGNITION AND TREATMENT OF CARBON TETRACHLORIDE POISONING

This information circular was prepared by the Safety Research Institute and referred to the Council on Industrial Health and others for review and acceptance preparatory to publication.

CARL M. PETERSON, M.D., *Secretary.*

The industrial importance of organic solvents is constantly increasing. This increase is accompanied with a growing recognition that all organic solvents are toxic and with the widespread installation of protective controls. Cases of solvent intoxication continue to occur, however, as the result of accidents, lack of information, carelessness on the part of workmen and inadequate precautions on the part of small "incidental" users.

Carbon tetrachloride, because of its complete nonflammability and its desirable physical and chemical properties, is one of the most widely used organic solvents. It is employed as a dry cleaning fluid, as a metal degreaser, as a rubber solvent, as a fire extinguishing agent, as a constituent of household cleaning fluids and for a variety of other industrial and nonindustrial applications. Like many other useful products, however, it is not always handled properly, particularly by new users who may not have familiarized themselves with the nature and prevention of its toxic effects.

Physicians and nurses may find helpful this survey of the literature on the diagnosis and treatment of carbon tetrachloride intoxication, which has been prepared with the assistance of physicians, industrial hygienists and the manufacturers of the solvent.

THE SIGNS AND SYMPTOMS OF CARBON TETRACHLORIDE POISONING

Toxic reactions to carbon tetrachloride may result from a single brief exposure to a high concentration of the vapor, from prolonged or repeated exposure to a moderately high concentration or from regular daily exposure to low concentrations in excess of known or accepted safe limits; from repeated contact of the skin with the liquid, or from ingestion of the liquid. In addition, some persons show allergic-type skin reactions resulting from a single contact with the liquid or symptoms of intoxication from contact with the vapor even though it is below the normally dangerous limit.

Obese persons, alcoholic addicts and undernourished individuals are likely to be especially susceptible to carbon tetrachloride injury, as are those with diabetes, liver or kidney disease, jaundice, pulmonary or heart disease or peptic ulcers. The assignment of such persons to work where they may be exposed to the solvent can be avoided by preplacement physical examination.

The signs and symptoms of poisoning from carbon tetrachloride differ somewhat according to the nature of the exposure:

1. A single exposure to a high vapor concentration may cause a feeling of fulness in the head and mental confusion, followed by headache, dizziness, nausea, stupor or loss of consciousness. Death due to respiratory failure may follow if the person is not promptly removed to a safe area. A heavy exposure may result in the delayed appearance of systemic poisoning with liver and kidney symptoms.

2. Repeated or prolonged inhalation of air containing unsafe concentrations of vapor may cause headaches, fatigue, nausea, vomiting, dizziness, visual disturbances and coughing of bloody mucus, followed in severe cases by acute nephritis, jaundice or toxic hepatitis. Injury to the central nervous system may occur.

3. Repeated contact with the skin removes the sebum and thus may result in redness, roughness, chapping and subsequent infections. The statement occurs occasionally in the literature that symptoms of systemic intoxication may result from prolonged skin contact, particularly in cases of burned areas or open cuts or wounds. It may be that symptoms attributed to absorption through the skin are due to inhalation of vapor at the time of skin contact.

4. Cases of poisoning by ingestion have been reported following the use of carbon tetrachloride as an anthelmintic. Effects are nausea, vomiting, abdominal distress, diarrhea, bloody stools, unconsciousness or coma. Later effects may be jaundice, cirrhosis of the liver and damage to the kidneys, heart, adrenal glands or nervous system. Intake of more than 3 to 4 cc. orally may cause death.

Intoxication with any one of a large number of industrial chemicals results in symptoms and syndromes similar to those listed. Most organic solvents, including benzene, methyl alcohol and carbon disulfide, and many metallic poisons as well, cause headache, vertigo, nausea and diarrhea. Symptoms of liver damage have been reported among the effects of intoxication with a wide variety of substances, including arsine, chlorinated naphthalenes, the chlorinated ethanes and occasionally benzene.

In many instances of acute poisoning by carbon tetrachloride the patient or his associates will know what toxic agent is concerned, but when products carrying brand names or solvent mixtures may be involved or in chronic exposure cases, a referral to carbon tetrachloride usually cannot be made on the basis of symptoms alone. The safety department at the plant where the patient is employed, or sometimes the industrial hygiene division of the local or state health department or labor department, may be helpful in identifying the nature of the patient's exposure.

Such authoritative assistance may also be useful in case the physician is later called on to give legal evidence in connection with the case.

THE TREATMENT OF CARBON TETRACHLORIDE POISONING

Contact with the Eyes.—The first step, if carbon tetrachloride spills or splashes into the eyes, is to wash them with large amounts of water for at least fifteen minutes. It is advisable to use a low pressure supply of water at room temperature in order to minimize the pain and discomfort caused by this procedure. Thereafter, symptomatic therapy should be employed if indicated.

Contact with the Skin.—Wash the skin thoroughly with a mild soap and warm water. After this an ointment containing petrolatum or lanolin should be applied in order to replace partially the natural skin oils. For cases of frank dermatitis or for signs and symptoms of generalized poisoning, symptomatic treatment is recommended.

Inhalation of the Vapor.—A person showing symptoms such as headache, nausea, dizziness or unconsciousness should be immediately removed to an area where the air is fresh and uncontaminated by carbon tetrachloride vapors. He should rest quietly and be kept warm. In case breathing has stopped, artificial respiration such as that obtained by the prone pressure or by the Eve rocking method should be used. If oxygen inhalation apparatus is available, oxygen should be administered. If the patient is conscious, hot tea or coffee may be given as a stimulant. An alcoholic stimulant or epinephrine should never be given to a person overcome by carbon tetrachloride.

Persons with only mild symptoms of solvent intoxication usually recover uneventfully under symptomatic treatment if they are protected from further inhalation of excessive amounts of solvent vapors. In more severe cases in which there are indications of liver or kidney involvement, carefully considered therapy is required. Hospitalization may be advisable for persons suffering from acute exposure.

Ingestion of the Liquid.—The first step is the prompt elimination of unabsorbed portions of the solvent, if it is suspected or known that a person has swallowed carbon tetrachloride. The patient should be made to vomit by drinking a glass of mustard water, lukewarm salty water or warm soapy water. If necessary the patient should be encouraged to stick his finger down his throat to induce vomiting. This procedure should be repeated at least three times. Following this, 1 tablespoon of epsom salt in water should be administered. (CAUTION: NEVER GIVE ALCOHOL, FATS, OILS OR EPINEPHRINE TO A PERSON WHO HAS BEEN EXPOSED TO CARBON TETRACHLORIDE.)

Symptoms of systemic illness should be watched for. They may develop quickly or they may be delayed several days.

SYSTEMIC THERAPY

The survey which follows is intended merely as a guide to the literature which has been published on this subject.

Davis and Hanelin,[1] who studied the problem of therapy after successfully treating a patient severely poisoned by inhalation, with renal involvement, made the following recommendations:

"Immediate removal or withdrawal of the poison is essential to successful treatment. If one bears in mind the complex clinicopathologic picture and disruption of the normal body chemistry, the treatment resolves itself into the following procedures:

"1. Intravenous hypertonic glucose and Hartman's solution to combat acidosis and liver dysfunction.

"2. Insulin in small doses, usually 2 to 3 units of U 20, to facilitate carbohydrate, fat and protein metabolism.

"3. Calcium gluconate[2] or calcium lactate, as recommended by Minot[3] and Cutler.[4]

"4. Papaverine hydrochloride or sulfate, an alkaloid of opium, ½ grain [32 mg.] intravenously where coronary, kidney and spastic states are present.

"5. Sodium decholin as a diuretic to facilitate the action of papaverine." [Some authorities state, however, that sodium decholin is given as a cholagogue; it may have slight diuretic effect, but diuretics do not facilitate the action of papaverine.]

"6. The xanthine diuretics to relieve the coronary embarrassment and to facilitate diuresis; however, we think the papaverine effect is slightly better.

"7. Never use epinephrine, since the Jourdans[5] have observed syncope subsequent to its use in carbon tetrachloride poisoning.

"8. Methylene blue may be used as recommended by Nelson,[6] but we have had no experience with this method." [Recent reports indicate that the use of methylene blue may be followed by untoward developments.]

"9. Oxygen inhalation may be necessary if pneumonic symptoms are present.

"10. The administration of a high carbohydrate diet is essential.

"11. Blood transfusion may be necessary for anemia."

According to Allison[7] "two drugs, calcium and glucose, are definitely indicated in the treatment of carbon tetrachloride poisoning."

Insulin and diuretics may not be necessary in every case. The danger of administering epinephrine in cases of carbon tetrachloride poisoning should be emphasized.

The amino acid methionine (dose 2 Gm. or more daily) has recently been used with success in therapy of several cases of carbon tetrachloride poisoning. Based on animal experimentation, treatment with choline chloride (2 to 5 Gm. daily) and cystine, together with a high protein, high carbohydrate, low fat diet, is suggested by one authority. A case of acute systemic poisoning resulting from accidental ingestion of a sizable amount of the solvent, reported by Beattie, Herbert, Wechtel and Steele,[8] was successfully treated with a combination of casein digest and methionine. Subsequently a series of 6 patients, 2 of them acutely ill, who had suffered industrial exposures to extremely high concentrations of carbon tetrachloride vapor, were successfully treated by Eddy[9] with intravenous glucose, a high protein, high carbohydrate and low fat diet, together with methionine, in doses of 2 Gm. every four hours. The most seriously ill of these patients received 68 Gm. of methionine during the course of treatment.

HEALTH AND WELFARE IN EMPLOYMENT CONTRACTS

The growing interdependence between industrial medicine, community medical services and public health administration was never more clearly demonstrated than in the negotiations resulting in the National Bituminous Coal Mines Wage Agreement. The terms of this contract between the mine workers and the government acting as operator of the soft coal mines are well known. They range from long overdue revision of safety codes and workmen's compensation benefits to direct participation by the union in the administration of funds for medical and hospital care and for general welfare. The medical profession seems to be sympathetic to all bona fide efforts to improve working and living conditions. The Council on Industrial Health, the Board of Trustees and the House of Delegates of the American Medical Association have approved the general policy of cooperative industrial health planning by management, labor and medicine, provided scientific and ethical standards are maintained.

The results of the comprehensive survey and study of the hospital and medical facilities, medical treatment, sanitary and housing conditions in the bituminous coal areas described by Boone elsewhere in this issue are indicative of the needs. The purpose is to raise the level of these facilities to recognized American standards The survey teams supplied by the Bureau of Medicine and Surgery of the U. S. Navy will present an objective report. Past investigations of the coal mine areas, and no doubt the present one, call attention to the shortcomings of contract practice, the advantages and disadvantages of industrywide medical and hospital care plans, the need for greatly expanded medical supervision over the physical status of workers and their working environment, the shortages in medical personnel and hospital facilities and the serious deterioration of standards of public health administration in the coal regions.

In spite of impending legislation, health and welfare are likely to be important factors in future collective bargaining. Labor may ask for greater direct participation not only in industrial medical service but in plans for general medical care. Both the Council on Industrial Health and the Council on Medical Service have been actively concerned with the medical implications in the coal mine wage agreement and the probable extension of similar contracts to other occupational groups. Herein lie many opportunities for constructive medical leadership. The medical profession obviously has great but not complete responsibility for standards of medical care and public health services. Enlightened elements in the community must assume their share of this burden, particularly in adequate local support. As far as the coal mine region is concerned, an early conference representing employers, employees and the medical profession is urgently indicated.

IMMUNOLOGIC ROLE OF MINERALS AND AMINO ACIDS

The association of famine with infectious diseases[1] and the many examples of increased susceptibility to intercurrent infection evidenced by hypoproteinemic patients[2] indicate a relationship between dietary factors and bacterial resistance. In his 1942 presidential address before the American Association of Immunologists Cannon[3] of the Department of Pathology, University of Chicago School of Medicine, suggested a theory that would account for this relationship. He pictured antibodies as specifically modified humoral globulins whose formation is dependent on protein intake and protein reserves.

Cannon and his associates[4] showed that decreased protein reserves brought about by prolonged low protein diets leads to a definite decrease in specific antibody production in laboratory animals. The antibody producing mechanism is not permanently damaged by such depletion, as shown by the fact that the antibody function may be restored to its original level by ingestion of adequate amounts of high quality proteins,[5] protein hydrolysates[6] or amino acids.[5] Increased antibody production is noted as early as two days after beginning this repletion and is restored to nearly normal by the end of seven days.

In a typical experiment, several groups of rats were placed on a low protein diet for one hundred and seventy-three days. During this time they lost some 35 per cent of their original body weight. There was a parallel fall in the percentages of hemoglobin and serum protein. Certain of these depleted animals were then changed to the same low protein diet, in which a mixture of sixteen crystalline amino acids modeled after the amino acid composition of casein was substituted for the same weight of corn starch.

[5] Wissler, R. W.; Woolridge, R. L., and Steffee, C. H.: Proc. Soc. Exper. Biol. & Med. **62**: 199 (June) 1946.

[6] Wissler, R. W.; Woolridge, R. L.; Steffee, C. H., and Cannon, P. R.: J. Immunol. **52**: 267 (March) 1946.

On the seventh day of this amino acid feeding each animal, together with an equal number of depleted controls, was injected intravenously with 1 cc. of 0.25 per cent washed sheep erythrocytes. Blood for antibody titration was taken at periodic intervals during the next ten days. The average maximum hemolytic titer of the depleted controls was 100 units. With animals given the amino acid feeding the average titer was between 500 and 600 units. The substitution of crystalline amino acids for carbohydrates thus increased antibody production at least fivefold. As much as a tenfold increase in antibody production was demonstrated in certain repletion experiments with high grade proteins (dehydrated beef) and a twentyfold increase with protein hydrolysate (amigen).

Cannon pictures his data as confirmation of his theory that antibody production is dependent on an adequate supply of essential amino acids coming either from food or from protein reserves. He believes that these repletion tests have a practical bearing on prophylaxis under famine conditions and on the preparation of debilitated patients for vaccination or surgical operations. These observations are applicable to man, as shown by Krebs[7] of the Department of Medicine, Washington University School of Medicine, who tested a patient with uncomplicated nutritional hypoproteinemia. The patient's gamma globulin was but 0.15 Gm. per hundred cubic centimeters, or about one-fourth normal. The patient was vaccinated against typhoid by three weekly injections of 1 billion killed typhoid bacilli. After completion of this immunization, the patient's serum did not contain a trace of antityphoid agglutinins. Detailed studies of the role of individual amino acids in specific antibody production are now in progress. Preliminary tests suggest that only eight of the sixteen amino acids in casein are essential for antibody production.[8]

A second, equally promising, new lead in nutritional immunity is reported by Elvehjem and Clark[9] of the Departments of Biochemistry and Bacteriology, University of Wisconsin Medical School, as a result of their study of the role of minerals in antiviral immunity. Eleven hundred Swiss mice from 21 to 24 days old were divided into groups of 20 to 35 mice each by the split litter technic, with consideration for sex and weight. The control mice were given a complete synthetic diet plus 4 per cent optimum salt mixture. Other groups were fed on the same ration, in which one or more of the essential minerals was reduced to a minimum. After eight to fifteen days on this depletion diet each animal was injected intracerebrally with a standard dose of Theiler's neurotropic virus.

In a typical experiment five groups of mice were placed on diets containing 0, 5, 15, 30 and 100 per cent of the optimum amount of potassium. Twenty-six per cent of those on the control (optimum) potassium diet became paralyzed within five days after inoculation, increasing to 91 per cent by the end of ten days. Among those without potassium, none became paralyzed before the sixth day, increasing to but 32 per cent by the end of ten days. In another group deprived of both sodium and potassium for twelve days only 18 per cent became paralyzed after inoculation with this neurotropic virus. Animals given intermediary doses of potassium showed intermediary percentages of paralysis.

Similar increases in natural resistance were shown in mice after ten to fifteen days of restricted intakes of phosphorus. A slightly less increased resistance was shown after restricted intake of sodium. Restricted intakes of calcium, magnesium or chlorine for the same length of time did not cause any change in antiviral resistance.

THE COMMISSION ON HOSPITAL CARE

The Commission on Hospital Care has just made available a condensation of the report of a two year study of "Hospital Care in the United States." The 700 page report offers 185 conclusions and recommendations for bringing better hospital care to the American people. Thomas S. Gates, LL.D., Philadelphia, chairman of the Commission on Hospital Care and chairman of the University of Pennsylvania, said "If this program fulfils the objectives it will become the blueprint for a voluntary organization and development of hospital services and facilities that will offer all people everywhere within our country an excellence of hospital care never heretofore attained." The Commission on Hospital Care was established as an autonomous study group at the suggestion of the American Hospital Association. The two year study was financed by contributions of $35,000 each from the W. K. Kellogg Foundation, the Commonwealth Fund and the National Foundation for Infantile Paralysis. The U. S. Public Health Service cooperated by assigning personnel to assist. The committee collaborated with local state groups in detailed studies of their needs and conducted a "pilot study" of Michigan assisted by the Michigan Hospital Association and state agencies. From experience in Michigan the commission developed its present report.

Soon after organization of the commission, Senators Hill and Burton introduced the legislation which culmi-

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Harold B. Hermann

The Bronze Star Medal was recently awarded to Lieut. Col. Harold B. Hermann, M. C., U. S. Army, Brooklyn, for meritorious achievement at Okinawa, Ryukyu Islands, from May 20 to Sept. 2, 1945 in connection with military operations against the enemy. In recounting his services the citation stated that, "as commanding officer of a station hospital, Lieutenant Colonel Hermann established a 400 bed hospital unit with maximum efficiency despite enemy air attacks and heavy rains which delayed the unloading of medical supplies and equipment. When the hospital was designated as the army evacuation center for Okinawa he performed this additional mission in such an outstanding manner that over 5,000 patients were processed and dispatched to rear areas without fatalities or serious mishaps. He demonstrated exceptional leadership and resourcefulness in maintaining high morale among both patients and staff and in making emergency improvisations to alleviate the overflow conditions which often existed. By his outstanding professional knowledge, administrative ability and devotion to duty, Lieutenant Colonel Hermann contributed substantially to the safe and efficient evacuation of sick and wounded army personnel from Okinawa and to the hospitalization program for that area." Dr. Hermann graduated from New York University College of Medicine, New York, and entered the service April 5, 1941.

MISCELLANEOUS

CAMPAIGN FOR FUND FOR NURSES MEMORIAL

The campaign to raise at least $2,500,000 for the Nurses National Memorial began throughout the country November 17. The memorial will be a tribute to the nurses who served in World War II and particularly to the 196 women of the Army Nurse Corps who lost their lives in the war. The campaign will continue until after New Years, and contributions will be sought from all citizens.

The memorial, to be erected in Washington, will be a home and center for upward of 100,000 women who will be eligible to use its facilities. The memorial will provide sleeping accommodations for at least 300 women, a lounge, library, assembly rooms, and dining and kitchen facilities.

Arthur H. Johnson, the national chairman, announced from the headquarters at 825 Woodward Building, Washington, D. C., that contributions will be sought from all citizens. In communities where chairmen have been established, these donations can be given to the local committee; otherwise they can be sent to National Headquarters in Washington. Thousands of hospitals, stores and other establishments will accept contributions by coin collectors or other means.

The memorial has been widely endorsed by leaders in all walks of life. One of the more recent additions to the list of sponsors is Cardinal Joseph Francis Spellman. At the recent meeting of Army chaplains in Washington, assembled for the sixteenth annual convention, the Chaplains Association of the Army and Navy unanimously endorsed the Nurses National Memorial campaign and urged all chaplains to lend their support to the project.

MEDICAL OFFICERS NEEDED FOR INDIAN SERVICE

The Department of the Interior announced on November 8 that medical officers were urgently needed for duty in the U. S. Indian Service. Preference will be given to former military personnel and federal employees. The entrance salary for recent graduates is $4,149.60 and for those who have had additional experience or special training $4,902 per annum.

Applicants must be graduates of an approved medical school and have successfully completed at least one year of internship in an approved hospital or its equivalent. Applicants must be American citizens and in good physical condition, but physical requirements are not as high as for the Army or Navy. When vacancies occur in the higher grade positions, promotions are made within the service whenever practicable. Government-furnished quarters are usually available at a cost of about $25 to $40 per month, and food costs are about the same as in any comparable rural area.

The Indian Service furnishes a unique complete medical service to Indian beneficiaries of all ages, mostly in rural areas within the United States and to the native population of Alaska. Appointments may be made to a hospital position or to a general practice on reservations. Most of the vacancies lie in the states west of the Mississippi River. Applicants may express a preference as to location. Appointments in Alaska have a 25 per cent differential in addition to base pay, and transportation of the appointee and his family and personal effects from place of actual residence to assignment in Alaska is paid by the government.

Interested physicians are urged to write to the Office of Indian Affairs, Merchandise Mart, Chicago 54, for further details and application forms.

PUBLIC HEALTH SERVICE

MEDICAL OFFICERS RELEASED FROM SERVICE

U. S. Public Health Service headquarters reports that the following medical officers have been terminated, inactivated, or retired, and directed to proceed to the city opposite their name:

Berman, Irving L., Senior Assistant Surgeon (R), Newton Center, Mass.

Callahan, Neil, Senior Assistant Surgeon (R), New Orleans.

Caplan, Sheldon M., Senior Assistant Surgeon (R), Chester, Pa.

N. Y.

Dillon, Milton, (R), Bronx,

N.

Lubitz, Joseph M., Surgeon (R), Milwaukee.

Marciano, Charles A., Surgeon (R), Brooklyn.

Miller, Arthur C., Senior Assistant Surgeon (R), Santa Rosa, Calif.

Olansky, Sidney, Senior Assistant Surgeon (R), Durham, N. C. (inactivation).

Rush, Willett H., Senior Assistant Surgeon (R), Versailles, Ky.

Rutecki, Vincent, Senior Assistant Surgeon (R), Buffalo.

Shack, Munroe E., Senior Assistant Surgeon (R), Somerset, N. J.

Taylor, Carl E., Assistant Surgeon (R), Cincinnati.

Treat, Michael R., Senior Assistant Surgeon (R), Philadelphia.

Camp, Wesley, Surgeon (R), Pueblo, Colo.

Clarence H., Medical Director, Pass Christian, Miss

Surgeon (R), New Orleans.

Assistant Surgeon (R), New York.

Senior Assistant Surgeon (R), Louisville.

Assistant Surgeon (R), Mauricetown,

nated in the Hospital Survey and Construction Act. Every state in the nation now has inaugurated or is organizing its own survey. The Hospital Survey and Construction Act authorizes $3,000,000 in federal assistance funds for surveys and $75,000,000 annually for each of five years for assistance in the actual construction of hospitals and public health centers, this amount to be augmented two to one by state or private funds. Thus the total amount of construction envisioned in the acts amounts to $1,125,000,000.

The conclusions and recommendations of the commission propose that governmental general hospitals in areas not adequately served by nongovernmental hospitals should function as community institutions but should not expand where nongovernmental facilities are meeting the need. Voluntary, nonprofit hospitals should be used to provide care to beneficiaries of the government whenever possible. The commission urges much closer coordination of special institutions (such as those for the care of the tuberculous, other chronically ill and nervous and mental patients) with general hospitals. The managing boards of hospitals, including governmental, church and private hospitals, the commission feels, should include representatives of the public. General hospitals, the commission holds, should make proper arrangements for the care and treatment of communicable diseases and for acute infantile paralysis. Either the special communicable disease hospitals now operated by cities, counties and states should be discontinued or their service should be expanded to provide care for other types of illness.

The commission proposes that hospitals make their diagnostic facilities generally available to all competent doctors in the community and that diagnostic clinics be established in the interests of both doctors and patients. When possible and desired, hospitals should provide office space for doctors and, when conditions permit, combine their efforts with those of the medical profession toward the extension of group medical practice. Rehabilitation of patients after illness, health education of both patients and the public, and coordination with public health departments are matters to which hospitals should give detailed consideration.

The report outlines a number of proposals for the registration of hospitals and for appraising the quality of the care they provide. All institutions providing overnight bed care for the sick should be licensed and should be subject to inspection by a state authority having the counsel of hospital administrators and professional personnel. To attract physicians and nurses to rural areas, the report favors special inducements, including regular visits to rural institutions by members of the faculties of medical colleges for clinics and educational meetings. Separate Negro hospitals should not be developed except in communities where such hospitals are required by law. In the latter instances as good hospital service for Negro patients as for white patients should be maintained. The report proposes the admission of qualified Negro physicians to hospital staffs, an increase in the number and employment opportunities of Negro nurses and full educational opportunities for Negro physicians and nurses. For better service to the people, the report urges interchange of hospital services and equipment among institutions to reduce costs and also the establishment of coordinating councils to assist close working relationships.

The report outlines principles which the commission believes should form the basis of any system of payment which may be adopted to insure wide distributions of hospital care and to make possible the maintenance of high standards of service. Federal aid may lift the level of hospital care in the low income states to a standard which would insure the good health of the nation. Concerted efforts need to be made by both governmental and private agencies to extend membership to nonprofit prepayment plans, according to the commission, until some other more satisfactory and comprehensive means are developed to meet all the needs of all the people. It recommends that any legislation which prescribes that hospital care insurance shall be obligatory should permit its purchase from any agency, public or private, which conforms to established standards of service and operation.

Citing the need for replacement of a large number of existing hospitals, the commission explains that perhaps 25 per cent of all hospital beds are in this category. The pilot study in Michigan yielded data which, projected for the nation as a whole, "indicate that the public need would be better served by approximately 40 per cent fewer but larger hospitals." At present costs the construction and equipping of the proposed new hospital facilities would approximate $1,800,000,000, the commission estimates. Operation of these additional facilities would add about $375,000,000 a year to the nation's hospital bill for the care of acute general illness. The nation's bill for care in general hospitals now amounts to some $1,006,000,000 annually. Another half billion dollars is expended yearly for the care of nervous and mental diseases, tuberculosis and other special illnesses.

While the report is concerned basically with general hospitals, it estimates that there is a need for 45,000 additional beds for tuberculous patients and it recommends that they be established in or near general hospitals where these can be converted to other use as the prevalence of tuberculosis declines. It cites an apparent need for additional nervous and mental facilities but states that detailed study and reorganization of methods of treatment and administration should come first.

Current Comment

DOCTORS THEN AND NOW

The centennial year of the American Medical Association will be recognized in a series of broadcasts over the stations and networks of the National Broadcasting Company; the title is "Doctors Then and Now." The theme and subtitle of the series will be "One Hundred Years of Progress in American Medicine." This broadcast, announced in detail on page 648 of The Journal, November 16, will be developed regionally. The progress of medicine in various areas of the United States will be recounted with the cooperation of the state medical societies. The event chosen by the medical profession in each region as its most significant or most interesting contribution to the progress of American medicine will be dramatized. The dramatization will come from Chicago, using the facilities of the National Broadcasting Company. Having pictured "Doctors Then" the broadcast will switch by means of specially leased wires to a radio station in the area which is the topic of that week's presentation. There a physician will be waiting to make a rapid summary of "Doctors Now" in that area. Each of these speakers will be a nominee of the medical profession in the area. A special mailing piece is being prepared to point up progress in American medicine in the hundred years since the American Medical Association was organized. These mailing pieces will be sent from the Chicago headquarters in response to inquirers who write for further information. The mailing pieces will also be available in quantities at a nominal charge for medical societies who choose to take over the distribution in their own area. Dates for the various regional broadcasts will be made known to medical societies in the respective areas in plenty of time for them to give wide publicity to these events. Publicity by state medical societies and local societies is envisioned not only through publications which reach the doctor but through press releases, local broadcasts, announcements by speakers and in any other way which seems most feasible locally.

THE NATIONAL CONFERENCE COMMITTEE ON WORKMEN'S COMPENSATION

The Council on Industrial Health was established in the structure of the American Medical Association to bring about better clinical and administrative care of persons injured by industrial accidents or incapacitated by occupational disease. The efforts to accomplish this purpose have recently been formalized through the organization of a National Conference Committee on Workmen's Compensation. First steps were taken in 1944, when representatives of the International Association of Industrial Accident Boards and Commissions, of the insurance companies' Combined Claims Committee and of the Council on Industrial Health of the American Medical Association outlined the need for a joint approach to the problem and elaborated a twelve point program. The simplification and uniformity of forms for reports, the adoption of a standard nomenclature and statistical methods, medical testimony, disability evaluation, rehabilitation, elevation of standards of medical care for the industrially disabled and greater participation in administration by medically trained people with essential administrative qualifications are problems of special interest to the physician. Most of these activities have been assigned to subcommittees which are empowered to seek technical advice and assistance from other interested groups and agencies. Other committees are concerned with administrative functions, for example, more prompt payment of compensation benefits and reductions in hearings and appeals. Since the early steps of organization, invitations to participate have been extended to the two national labor groups, the National Association of Manufacturers, the Chamber of Commerce of the United States, the Bureau of Labor Standards of the United States Department of Labor and more recently to the National Association of Self Insurers. The results of committee investigation and specific recommendations are to be submitted to each participating organization for additional study and debate and, if necessary, ratification. Already some excellent foundation work has been accomplished. Medicine has much to contribute in the broad field of compensation administration and, even more, in the intimate details of case management. One of the principal planks in the program of the Joint Conference Committee states that the work of the committee must be fundamentally in the best interests of the individual worker.

THE CARE OF CHILDREN IN DAY NURSERIES

The great influx of married women into industry during the war years led to a rapid increase in day nurseries, many of which were poorly equipped and inadequately staffed. In some of these institutions conditions existed which were reminiscent of the novels of Charles Dickens—they were being operated largely for the profit of the proprietor and with little if any attention to the needs of the children. Even in the best of these nurseries, problems of communicable disease control and of nervous fatigue brought about by an excessively stimulating environment were serious and the need for a planned and cooperative attack on these problems became evident quite early in the development. Two pamphlets recently published by the Child Welfare League of America, Inc., offer many useful suggestions and guide lines for physicians, educators, nurses, social workers, sanitarians, nutritionists, psychologists and all other workers associated in any way with day nurseries. The first of these, "Daytime Care—A Partnership of Three Professions," reports the findings of a triprofession conference on day care held June 11-15, 1945 at Old Lyme, Conn. The second, "The Day Care of Little Children in a Big City," explains the work of the Day Care Unit which has been operating in the New York City Department of Health (Bureau of Child Hygiene) since 1943. These pamphlets, which should be read by all physicians connected with day nurseries, are procurable from the Child Welfare League of America, Inc., 130 East Twenty-Second Street, New York 10.

ORGANIZATION SECTION

Official Notes

RESOLUTION TO BE PRESENTED TO HOUSE OF DELEGATES

The following resolution has been submitted by Dr. A. S. Giordano, a member of the House of Delegates representing the Indiana State Medical Association:

Resolution on Intern and Resident Medical Training

Whereas, The primary objective of intern and resident medical training is medical education; and

Whereas, The acceptability of internships and residencies in hospitals should be founded on the excellence of their teaching programs; and

Whereas, The number of hospitals approved for intern and resident training exceeds the number of available interns and residents; and

Whereas, Such disparity has forced hospitals to compete for applicants for training on monetary rather than on educational opportunities; therefore be it

Resolved, That a reasonable and uniform maximum figure for the remuneration of interns and residents be established, so that the monetary value of internships and residencies may not act as a deciding factor in the applicants for such training.

Washington Letter

(From a Special Correspondent)

Nov. 25, 1946.

Newspaper Calls Delay in Modernizing Prosthetic Devices "Artificial Limb Disgrace"

In an editorial entitled "Artificial Limb Disgrace" the Washington *Daily News* and some twenty-one other Scripps-Howard newspapers have criticized the manufacturers of artificial limbs for alleged failure to incorporate reported modern improvements in the new prosthetic devices now being manufactured. "These improvements, according to Gen. G. B. Erskine, director of reemployment and retraining, have failed to materialize on the production line," the editorial states, continuing "His statement confirms many reports of bitter disappointment when amputees compared what was offered them with what the morale builders had promised. The manufacturers complain that skilled help is lacking. The principal trouble seems to be a lack of imagination and enterprise. Here is a problem involving the honor of the government and of the whole people, a problem where expense is no object."

Dr. Martha Eliot First Woman President of the American Public Health Association

Dr. Martha M. Eliot, associate chief of the Children's Bureau, will become the first woman president of the American Public Health Association in its seventy-five years of history, following her appointment as president-elect at the recent convention in Cleveland. She will take office at the 1947 session in Atlantic City next fall, the newly installed president being Dr. Harry S. Mustard, director of the DeLamar Institute of Public Health at Columbia University. Dr. Eliot was vice chairman of the United States delegation at the world health conference in New York. She is a Fellow of the American Medical Association, the American Academy of Pediatrics and the American Public Health Association. She is internationally known as a pioneer in the study and prevention of rickets.

National Drug Trade Conference Asks Tighter State Laws on Sleep Producing Drugs

The National Drug Trade Conference has asked for a tightening of state laws to prevent illegal use of sleep producing drugs such as the barbiturates, which are sedatives in action and frequently are prescribed by physicians to produce sleep or quiet nervous conditions. Dr. Austin Smith, director of the division of therapy and research of the American Medical Association, told the meeting of drug representatives, called to consider what controls should be requested, that the "potential harm" of such drugs is "habituation, suicide and possibly murder."

New Pox Disease Identified at National Institute of Health

Three scientists at the National Institute of Health are reported to have described and identified a new disease closely related to chickenpox and spotted fever, which has been named rickettsialpox. Considered the mildest of infections of its type, the disease was studied at or near a large housing development in New York by Drs. Robert J. Huebner and Charles Armstrong and Miss Peggy Stamps, bacteriologist.

Council on Medical Service

NORTH CENTRAL MEDICAL CONFERENCE

The annual meeting of the North Central Medical Conference this year was coordinated with the regional meeting of the Council on Medical Service. The meeting was held in St. Paul on Sunday, November 10. The conference president, Dr. J. D. McCarthy of Omaha, acted as chairman for the day.

Although it was but a one day meeting, many subjects and problems were presented and discussed. The speakers and subjects were:

"The American Medical Association as an Instrument to Advance the Ideals of American Medicine," Dr. J. D. McCarthy, Omaha.

"Public Relations of the American Medical Association," Thomas A. Hendricks, Secretary, Council on Medical Service, A. M. A.

"Medical Care in Rural Areas," Dr. L. W. Larson, Bismarck, N. D.

"National Legislation," Mr. J. W. Holloway Jr., Chicago, Director, Bureau of Legal Medicine and Legislation, A. M. A.

"The Council on Medical Service," Dr. E. J. McCormick, Toledo, Ohio, Chairman, Council on Medical Service.

"Prepayment Medical Care Plans," Dr. A. W. Adson, Rochester, Minn., member of the Council on Medical Service, A. M. A.

"United Mine Workers Health Fund," Dr. C. M. Peterson, Secretary, Council on Industrial Health, A. M. A.

"Medical Care for the Veteran," Dr. G. D. Williams, Veterans Administration, Washington, D. C.

"Hospital Survey and Construction Program," Dr. Herman E. Hilleboe, Assistant Chief, Bureau of State Services, U. S. P. H. S., Washington, D. C.

The following officers were elected to serve the North Central Conference for the coming year:

President, Dr. William Duncan, Webster, S. D.
President-Elect, Dr. A. W. Adson, Rochester, Minn.
Secretary-Treasurer, R. R. Rosell, St. Paul.

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec. 9-11. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.
Conference of State Secretaries and Editors, Chicago, Dec. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Dermatology and Syphilology, Cleveland, Dec. 7-12. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.
American College of Surgeons, Cleveland, Dec. 16-20. Dr. Dallas B. Phemister, 40 E. Erie St., Chicago 11, Secretary.
American Society of Anesthesiologists, New York, Dec. 12. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York, Secretary.
Post Graduate Medical Assembly of South Texas, Houston, Dec. 3-5. Dr. M. B. Stokes, 229 Medical Arts Bldg., Houston, Secretary.
Puerto Rico, Medical Association of, Santurce, Dec. 13-15. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.
Radiological Society of North America, Chicago, Dec. 1-6. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.
Southeastern Allergy Association, Atlanta, Ga., Jan. 18-19. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.
Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.
Western Surgical Association, Memphis, Tenn., Dec. 5-7. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

ARMY

SURGEON GENERAL ASKS YOUNG DOCTORS TO CONSIDER ARMY CAREERS

The War Department has authorized the commissioning of about 1,600 doctors in future integrations of Medical Corps officers. All doctors who received their medical education in the Army Specialized Training Program during the war have been given information regarding a career in the regular Army.

In letters sent November 15 to some 5,000 army doctors Major Gen. Norman T. Kirk, the Surgeon General, pointed out the professional advantages gained by practicing medicine in the peacetime regular Army. General Kirk said that the service offers thirty years of work in the field of medicine and its various specialties, which service will be devoted not only to active duty as doctors but to advance study in leading civilian medical schools when merited and in army general hospitals. An important point for doctors planning an army career is that younger men will be used entirely for professional assignments and training. Administrative positions are adequately provided from among the older officers. The army doctor begins to specialize in military medicine and surgery as soon as he enters the service. Complete and modern laboratories and medical equipment are available to him, and he is under the constant tutelage of experienced army doctors and prominent civilian medical scientists appointed as consultants to the Secretary of War through the Surgeon General. All applicants must be graduates of approved medical schools before they will receive consideration for commissions. The War Department has waived certain qualifications demanded of all army doctors, such as four years of medical studies and a year's internship in the case of ASTP trained doctors who received medical degrees under the accelerated program which required three years of medical study and nine months' internship. Approved internships, residency training and residency specialists training programs are in operation in army hospitals whereby a doctor trained in the abbreviated wartime program may enlarge on his education while receiving steady pay as an army doctor.

In considering the inducements offered by a career in the regular Army, General Kirk emphasized six principal points:

1. Professional assignments for those medical officers who desire them will be provided to the maximum extent possible.
2. Approved internships, mixed residencies and specialist residencies have been established in army hospitals.
3. Provision of specialist training in army hospitals and civilian institutons in order that regular army medical officers may qualify for the various American specialty boards.
4. Regular army medical officers will be encouraged to seek certification by the specialty boards.
5. Administrative training opportunities will be made available to those officers interested in administrative or tactical unit assignments.
6. Medical officers will be relieved to the maximum extent of tactical and administrative assignments for purely professional work.

The initial annual salary received by a first lieutenant is $3,804 if he has dependents and $3,372 if he has no dependents. The annual salary received increases with length of service and higher rank.

FOOD TASTERS AID IN RESEARCH ON FOODS

At the Quartermaster Food Institute for the Armed Forces, Chicago, under the guidance of a civilian committee, subsistence experts are endeavoring to find foods with satisfactory military requirements, utilizing carefully selected food tasters to help in the research. They have found that about 20 persons out of 100 have taste perceptions so accurate that they can tell the difference between canned bread that has been stored for two weeks at 70 F. and a similar item stored for the same length of time at 100 F. Some persons, the tests revealed, cannot distinguish the difference between a glass of clear water and one heavily saturated with quinine. A good taster, the experts say, will be right 12 or 13 out of 15 trials. The taste testing program is another step in research directed toward the goal of making foods more acceptable.

The Quartermaster scientists are endeavoring to learn which foods will retain their original characteristics longest and under high storage temperatures. They want to know which types of food are best, which types of container are preferable and whether foods maintain their stability better when vacuum packed or packed in inert gases. Highly qualified tasters are necessary for this work. Chemistry will indicate what changes have taken place in a food, but it will not reveal how these changes affect the human taste.

Another phase of food tasting conducted at the Quartermaster laboratories is testing items for preference. This problem involves the food preferences of all the men in the military service. To obtain percentages of preference, the scientists are employing large groups of testers not screened for their keenness of perception. Field ration items have been submitted to large messes at military installations and specialized items for sick or canvalescent personnel have been tested at army hospitals. The testing goes on continuously on fresh meats, vegetables and fruits, canned foods of all kinds and frozen foods.

RARE MANUSCRIPT AT ARMY MEDICAL LIBRARY

Probably the only manuscript extant of three medical works by the great Italian physician of the thirteenth century Taddeo Alderotti de Florentie is now on display in the Army Medical Library, Washington, D. C. This manuscript, written about 1375, is bound in three volumes, with rubrication in red and blue. Taddeo was the founder of the dialectical method in medicine. He was regarded as the most illustrious physician of all Italy, and it is possible that Dante, who immortalized him, attended his lectures at Bologna. Taddeo originated the form of medical literature called Consilia, a collection of clinical cases which had considerable vogue up to the end of the seventeenth century.

AVIATION MEDICAL EXAMINERS

Fifty-five officers of the Medical Corps graduated from the course for aviation medical examiners at the School of Aviation Medicine, Randolph Field, Texas, on October 19. The exercises included also musical selections by the 633d AAF band. The nine weeks course is designed to instruct AAF medical officers to be proficient in the special duties required of an aviation medical examiner, to familiarize them in the coordination of such duties with other professional and nonprofessional activities which they may be called on to perform and to indoctrinate them in flying training.

BRIGADIER GENERAL REINARTZ RETIRES

After twenty-nine years of military service, Brig. Gen. Eugen C. Reinartz, former commandant of the AAF School of Aviation Medicine, Randolph Field, Texas, will retire from active service with the Army. General Reinartz was assigned to the Aeronautics Division of the Aviation Section, Signal Corps, in 1919, and he has had continuous service with aeronautics since that date. He went to the North African and English theaters of war as aeromedical observer to study the problems confronting the flight surgeons in combat. In 1943 he received the John Jeffries Award for exceptional contributions to the advancement of aeronautics through medical research, given by the Institute of Aeronautical Sciences. He has had the longest continuous service of any medical officer assigned to the Army Air Forces, having known no other service in his entire army career.

Dr. and Mrs. Reinartz will make their home at 1518 Hearst Avenue, Berkeley 3, Calif. He contemplates entering private practice in neuropsychiatry in the San Francisco area.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Harold B. Hermann

The Bronze Star Medal was recently awarded to Lieut. Col. Harold B. Hermann, M. C., U. S. Army, Brooklyn, for meritorious achievement at Okinawa, Ryukyu Islands, from May 20 to Sept. 2, 1945 in connection with military operations against the enemy. In recounting his services the citation stated that, "as commanding officer of a station hospital, Lieutenant Colonel Hermann established a 400 bed hospital unit with maximum efficiency despite enemy air attacks and heavy rains which delayed the unloading of medical supplies and equipment. When the hospital was designated as the army evacuation center for Okinawa he performed this additional mission in such an outstanding manner that over 5,000 patients were processed and dispatched to rear areas without fatalities or serious mishaps. He demonstrated exceptional leadership and resourcefulness in maintaining high morale among both patients and staff and in making emergency improvisations to alleviate the overflow conditions which often existed. By his outstanding professional knowledge, administrative ability and devotion to duty, Lieutenant Colonel Hermann contributed substantially to the safe and efficient evacuation of sick and wounded army personnel from Okinawa and to the hospitalization program for that area." Dr. Hermann graduated from New York University College of Medicine, New York, and entered the service April 5, 1941.

MISCELLANEOUS

CAMPAIGN FOR FUND FOR NURSES MEMORIAL

The campaign to raise at least $2,500,000 for the Nurses National Memorial began throughout the country November 17. The memorial will be a tribute to the nurses who served in World War II and particularly to the 196 women of the Army Nurse Corps who lost their lives in the war. The campaign will continue until after New Years, and contributions will be sought from all citizens.

The memorial, to be erected in Washington, will be a home and center for upward of 100,000 women who will be eligible to use its facilities. The memorial will provide sleeping accommodations for at least 300 women, a lounge, library, assembly rooms, and dining and kitchen facilities.

Arthur H. Johnson, the national chairman, announced from the headquarters at 825 Woodward Building, Washington, D. C., that contributions will be sought from all citizens. In communities where chairmen have been established, these donations can be given to the local committee; otherwise they can be sent to National Headquarters in Washington. Thousands of hospitals, stores and other establishments will accept contributions by coin collectors or other means.

The memorial has been widely endorsed by leaders in all walks of life. One of the more recent additions to the list of sponsors is Cardinal Joseph Francis Spellman. At the recent meeting of Army chaplains in Washington, assembled for the sixteenth annual convention, the Chaplains Association of the Army and Navy unanimously endorsed the Nurses National Memorial campaign and urged all chaplains to lend their support to the project.

MEDICAL OFFICERS NEEDED FOR INDIAN SERVICE

The Department of the Interior announced on November 8 that medical officers were urgently needed for duty in the U. S. Indian Service. Preference will be given to former military personnel and federal employees. The entrance salary for recent graduates is $4,149.60 and for those who have had additional experience or special training $4,902 per annum.

Applicants must be graduates of an approved medical school and have successfully completed at least one year of internship in an approved hospital or its equivalent. Applicants must be American citizens and in good physical condition, but physical requirements are not as high as for the Army or Navy. When vacancies occur in the higher grade positions, promotions are made within the service whenever practicable. Government-furnished quarters are usually available at a cost of about $25 to $40 per month, and food costs are about the same as in any comparable rural area.

The Indian Service furnishes a unique complete medical service to Indian beneficiaries of all ages, mostly in rural areas within the United States and to the native population of Alaska. Appointments may be made to a hospital position or to a general practice on reservations. Most of the vacancies lie in the states west of the Mississippi River. Applicants may express a preference as to location. Appointments in Alaska have a 25 per cent differential in addition to base pay, and transportation of the appointee and his family and personal effects from place of actual residence to assignment in Alaska is paid by the government.

Interested physicians are urged to write to the Office of Indian Affairs, Merchandise Mart, Chicago 54, for further details and application forms.

PUBLIC HEALTH SERVICE

MEDICAL OFFICERS RELEASED FROM SERVICE

U. S. Public Health Service headquarters reports that the following medical officers have been terminated, inactivated, or retired, and directed to proceed to the city opposite their name:

Berman, Irving L., Senior Assistant Surgeon (R), Newton Center, Mass.
Callahan, Neil, Senior Assistant Surgeon (R), New Orleans.
Caplan, Sheldon M., Senior Assistant Surgeon (R), Chester, Pa.
Dillon, Milton, Assistant Surgeon (R), Jamaica, N. Y.
Di Pasca, Robert V., Senior Assistant Surgeon (R), Bronx, N. Y.
Dowdy, Kemp H., Senior Assistant Surgeon (R), Everett, Wash.
Eckberg, Edward M., Senior Assistant Surgeon (R), Galva, Ill. (inactivation).
Flick, Edward, Assistant Surgeon (R), Philadelphia.
Greer, Walter G., Senior Assistant Surgeon (R), Los Angeles.
Hruby, Allen J., Assistant Surgeon (R), Chicago.
Katz, David, Senior Assistant Surgeon (R), Clayton, Mo.
Ligon, Charles H., Assistant Surgeon (R), Brinklow, Md.
Lubitz, Joseph M., Surgeon (R), Milwaukee.
Marciano, Charles A., Surgeon (R), Brooklyn.
Miller, Arthur C., Senior Assistant Surgeon (R), Santa Rosa, Calif.
Olansky, Sidney, Senior Assistant Surgeon (R), Durham, N. C. (inactivation).
Rush, Willett H., Senior Assistant Surgeon (R), Versailles, Ky.
Rutecki, Vincent, Senior Assistant Surgeon (R), Buffalo.
Shack, Munroe E., Senior Assistant Surgeon (R), Somerset, N. J.
Taylor, Carl E., Assistant Surgeon (R), Cincinnati.
Treat, Michael R., Senior Assistant Surgeon (R), Philadelphia.
Van Camp, Wesley, Surgeon (R), Pueblo, Colo.
Waring, Clarence H., Medical Director, Pass Christian, Miss (retirement).
Williams, Ford S., Surgeon (R), New Orleans.
Woloshin, George, Assistant Surgeon (R), New York.
Woodard, Robert L., Senior Assistant Surgeon (R), Louisville.
Wright, Samuel, Senior Assistant Surgeon (R), Mauricetown, N. J.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Personal.—Dr. David R. Lyman, director of Gaylord Farms, Wallingford, was elected to honorary membership in the Connecticut Tuberculosis Association at its seventh annual meeting in New Haven, October 30, in recognition of the forty years he has devoted to his work in tuberculosis.——Dr. John D. Booth, Danbury, has been appointed to the Connecticut Medical Examining Board to fill the unexpired term of Dr. Daniel C. Patterson, recently deceased.

Course for Laymen in Mental Health.—The first in a series of orientation courses for laymen in the problems of mental health was held at the Connecticut State Hospital, Middletown, October 30. Sponsored by the joint committee of the state mental hospitals, the all day conference was attended by approximately twenty-five representatives of the press, clergymen and social workers. The program featured talks by officials of the hospital, motion pictures, panel discussions and study groups.

Rehabilitation Group Formed.—The Connecticut Rehabilitation Association was organized in Hartford, October 30, to promote the general cause of rehabilitation for mentally or physically disabled children and adults. Col. James M. Quinn, New Haven, chairman of the State Veterans Reemployment and Advisory Commission, was elected president of the organization; Randall Hamerick, Ph.D., Bridgeport, vice president, and Frederick W. Novis, acting director of the state board of education, secretary-treasurer. According to the constitution adopted at the meeting, the organization will "encourage and stimulate within Connecticut programs of guidance, physical restoration, training and placement in employment for all groups of disabled persons; promote and encourage the development of rehabilitation centers, and affiliate with the National Rehabilitation Association, Inc." About two hundred representatives of medicine, education, social welfare and industry attended the organization meeting.

DISTRICT OF COLUMBIA

Early Ambulation and Rapid Rehabilitation.—A symposium on "Early Ambulation and Rapid Rehabilitation of Hospitalized Patients" was conducted in Washington, November 13, with the following speakers: Dr. Howard A. Rusk, New York, guest speaker; Dr. Hugh H. Hussey Jr., medicine; Dr. James R. Veal, surgery, and Dr. William D. Terrell Jr., obstetrics. A joint meeting of the Medical Society of the District of Columbia and the Baltimore City Medical Society was addressed by Dr. John H. Mulholland, New York, on "Maintenance of Fluid Balances in Surgical Patients." This meeting marks the resumption of an old custom, abandoned during the war, of the Baltimore society meeting jointly with the Medical Society of the District of Columbia.

Graduate Work in Ophthalmology.—The George Washington University department of ophthalmology is planning the resumption of the intensive postgraduate courses in ophthalmology, the next course to be given the week of February 3-8 inclusive. These courses were discontinued during the war. The following guest lecturers are assisting the resident staff on the program:

Dr. Francis H. Adler, Philadelphia.
Dr. James Baird, Atlanta, Ga.
Dr. Sylvester Judd Beach, Portland, Maine.
Dr. Hermann M. Burian, Boston.
Dr. Ramon Castroviejo, New York.
Dr. Clyde A. Clapp, Baltimore.
Dr. Francis B. Fralick, Ann Arbor.
Deane B. Judd, Ph.D.
Dr. Peter C. Kronfeld, Chicago.
Dr. Walter I. Lillie, Philadelphia.
Dr. Angus L. MacLean, Baltimore.
Mr. Philip L. Salvatori, New York.
Dr. Harold G. Scheie, Philadelphia.
Dr. Edmund B. Spaeth, Philadelphia.
Dr. Frederick W. Stocker, Durham, N. C.

The tenth annual postgraduate course in ocular surgery, pathology and orthopedics will be given during the week of January 27-February 1. This is a practical course and is limited to thirty participants. For further details of the postgraduate courses in ophthalmology write to the secretary, Mary E. Kramer, Suite 34, 1801 K Street N.W., Washington 6.

IOWA

Personal.—Dr. Donald M. Harris has resigned as director of health district number 4, with headquarters in Sioux City, to accept a similar position of the Chippewa County Health Unit at Sault St. Marie, Mich. District number 4 includes the counties of Woodbury, Plymouth, Monona, Crawford and Ida.——Dr. Joseph A. Uran, Riceville, recently completed his fiftieth year in the practice of medicine.

KENTUCKY

Physician Honored.—Dr. John E. Kincheloe Day was observed in Hardinsburg recently to honor the physician who has practiced in the county for forty-seven years. One feature of the celebration was the starting of a drive for funds for a county hospital to serve as a memorial to the physician. Dr. Kincheloe was recently presented with the E. M. Howard Memorial Award of the Kentucky Medical Association (THE JOURNAL, November 9, p. 591).

MASSACHUSETTS

Experimental Study of Diabetes.—The entire population of the town of Oxford, 5,100 men, women and children, on October 7 became "guinea pigs" in a form of experiment to check the spread of diabetes, according to the New York *Sun.* It was stated that this was the first time that a whole community would be tested for diabetic symptoms. It was planned to obtain blood and urine specimens for laboratory examinations, the reports going to private physicians within two days for "quick treatment."

MISSISSIPPI

Societies Merge.—The North Mississippi and the Northeast Mississippi Medical Societies merged October 17, retaining the name North Mississippi Medical Society. Dr. Ashford A. H. Little, Oxford, was named president.

Loans to Medical Students.—Applications for loans to medical students to become effective in February 1947 will be received at the state medical education board offices in Jackson, beginning November 1. Scholarship loans are made available to worthy Mississippi men and women attending medical school by a program authorized by the 1946 legislature. Recipients of such loans sign a state contract to return to rural Mississippi for a period of two to five years following completion of medical education and one year internship. Interested persons should address inquiries to Mrs. Maria Voskamp, Executive Secretary, Mississippi State Medical Education Board, Room 37, 200 North Street Building, Jackson. New application forms have been prepared and are now ready for distribution. Students wishing to be considered for February scholarship grants are urged to get in touch with the state medical education board immediately.

NEBRASKA

Ninety Years of Age.—Dr. Martha E. Clark, who practiced medicine in Omaha twenty-eight years, celebrated her ninetieth birthday October 24. Dr. Clark graduated at Hahnemann Medical College and Hospital, Chicago, in 1897.

NEW MEXICO

State Medical Election.—Dr. Victor Adams, Raton, was named president-elect of the New Mexico Medical Society at its recent meeting, and Dr. Charles A. Miller, Las Cruces, was installed as president. Other officers include Dr. Donat F. Monaco, Gallup, vice president, and Dr. Harold L. January, Albuquerque, secretary-treasurer.

NEW YORK

Personal.—Dr. Robert E. A. Milne, Le Roy, has been appointed a member of the board of education of Rochester.——Dr. Charles B. Perkins, Franklinville, has been appointed coroner of Cattaraugus County to succeed the late Dr. Halley W. Hammond.——Dr. Harold J. Harris, Westport, gave the introductory speech and first lecture before the V. Reunion para el Estudio de la Brucelosis, October 28-November 2. The title of the lecture was "The Opsonocytophagic Test in Brucellosis; Some Observations on Its Technical Factors, Uses and Limitations."

New York City

Lectures on the Cardiovascular System.—Dr. Eric Ogden, visiting professor, New York University College of Medicine, and professor of physiology, University of Texas Medical Branch, Galveston, opened a series of three lectures November 6 on the cardiovascular system. The first lecture was on Experimental Hypertension and Its Extrarenal Sequel , the second, November 13 on 'The Function of the Cardiovascular System and Its Regulation," and the third, November 20, on 'Cardiovascular Integration by Endocrine and Nervous Mechanisms"

Recent Advances in Therapy—The Mount Sinai Hospital of New York will begin a series of lectures on recent advances in therapy, December 4, with a talk by Dr John G Gibson II, Boston, on "Advances in Blood Transfusion Therapy" Others in the series will be

Dr William Dock Brooklyn December 18 Physiologic Problems in the Treatment of Heart Disease
Dr Arthur J Patek Jr, January 8, The Dietary Treatment of Cirrhosis of the Liver
George R Cowgill PhD New Haven January 22 Recent Advances in Our Knowledge of Vitamins
Dr Hiram Merritt February 19 The Treatment of Epilepsy
Dr Sidney C Madden Atlanta Ga March 5 Amino Acid Therapy
Dr Alvan L Barach March 19, Physiological Therapy in Diseases of Respiration
Dr Lester R Dragstedt Chicago April 2 Section of the Vagus Nerves to the Stomach in the Treatment of Peptic Ulcer
Dr Edwin B Astwood Boston April 16 The Medical Treatment of Hyperthyroidism

Cancer Hospital Planned by City.—Plans were filed November 1 for a new 300 bed, twelve story city hospital for the treatment of chronic cancer patients The hospital will be built on the east side of First Avenue between Sixty-Seventh and Sixty Eighth streets The cost, according to the plans filed with the Department of Housing and Building will be $2 900 000 the New York *Times* stated November 2 Land for the new hospital was donated to the city by the Memorial Hospital, Dr Edward M Bernecker commissioner of hospitals, explained With Memorial Hospital and the new Sloan-Kettering Institute for Cancer Research now under construction the city's hospital will be one unit of a center devoted to the study and treatment of cancer When the building is completed some time in 1948, Memorial Hospital will nominate the staff and will also make available to the city institution its treatment facilities Thus the city will be spared the cost of duplicating expensive x-ray treatment equipment According to the plans the city hospital will contain laboratories, operating rooms, offices, classrooms, wards and living quarters for the hospital staff The offices and laboratories will be on the first floor classrooms on the mezzanine, and wards and utility rooms on the next seven floors Living quarters will be on the tenth floor a dining room on the eleventh floor and an apartment on the twelfth floor A penthouse also is included in the plans

OHIO

Student Prize—Through the cooperation of Mead Johnson and Company and the Museum of the Cleveland Medical Library, a prize of $100 is offered to the student in the school of medicine of Western Reserve University submitting the best thesis on a subject relating to the history of medicine It is suggested that exhibits in the museum might furnish leads for such an essay The award will not be made unless the quality of the articles submitted warrants such action Contributions should be typewritten in double space on good white paper and on one side of the sheet only The thesis must be long enough to provide a convincing argument and short enough to maintain interest All manuscripts shall become the property of the Cleveland Medical Library They must be mailed to the director of the Howard Dittrick Museum of Historical Medicine, 11000 Euclid Avenue, not later than March 1

PENNSYLVANIA

Philadelphia

Julius Comroe Promoted.—Dr Julius H Comroe Jr, formerly assistant professor of pharmacology, University of Pennsylvania School of Medicine, has been appointed professor of physiology and pharmacology in the university s graduate school of medicine

Clinic Named for Physician—The new 18 bed clinic for the hospitalization of alcoholic addicts at St Luke s Hospital has been named the Charles Dudley Saul Clinic in honor of the medical director of the hospital Credit goes to Dr Saul for development of the clinic In the first four months of its operation the clinic has cared for 238 patients

Hospital News—Tumor Day was observed at the Jewish Hospital November 19 with combined pathologic, radiologic and oncologic conferences presided over by Dr Fred W Stewart, Memorial Hospital New York Another session will be addressed by Dr Charles F Geschickter, Baltimore, on 'Recent Advances in the Etiology and Treatment of Cancer '

SOUTH CAROLINA

Allergy Meeting.—The second annual meeting of the Southeastern Allergy Association will be held January 18-19 at the Atlanta-Biltmore Hotel, Atlanta, Ga. Hotel reservations should be made directly with the hotel Dr. Hal M Davison, Atlanta, is president of the Southeastern Allergy Association, Dr. J Warrick Thomas, Richmond, Va, vice president, and Dr Emma B MacInnis, Columbia, S C, secretary-treasurer.

First State Health Officer.—South Carolina is said to be the first state to have had a state health officer, according to the book on Government in Public Health by Dr Harry S Mustard, New York The health officer was appointed by a special act of the general assembly of South Carolina The act of 1712 was repealed in 1721. In 1908 the general assembly passed another act creating the office The first state health officer appointed under the 1908 act was Dr Charles F. Williams, Columbia In 1911 he resigned and was succeeded by Dr. James A Hayne, Columbia, who served continuously for thirty-three years before resigning in 1944, when he was succeeded by Dr Benjamin F Wyman, Columbia

TENNESSEE

Changes in Health Officers—Dr John M Weir Jr, New York, has been named health officer of the Obion-Lake County Health Unit, filling the vacancy that occurred when Dr. William L Phillips resigned last October to enter private practice at Newbern——Dr Price H Duff, formerly of Crassville, has been appointed health officer of Rutherford County, Murfreesboro, succeeding Dr James B Black, who resigned, effective July 1, to enter the private practice of medicine——Dr Walter C Humbert, Erwin, has been appointed director of Giles and Lincoln counties——Dr George K Henshall Jr, Chattanooga, has been named director of the division of maternal and child health, Chattanooga-Hamilton County Health Department, to succeed Dr Rutherford O Ingham

TEXAS

Special Lectures—At the seventeenth annual meeting of the Texas Association of Obstetricians and Gynecologists in Galveston November 2 the Calvin R Hannah Lecture was delivered by Dr William F Mengert, Iowa City, on "Pelvic Cellulitis and the J J Y Paine Lecture by Dr John Rock, Boston on 'Menstrual Disorders" At a special postgraduate conference in cooperation with the maternal and child health division of the Texas State Board of Health and the department of pediatrics of the University of Texas Medical Branch, Galveston, during the week of October 28 Dr Daniel C Darrow, New Haven, gave the William Buchanan Lecture on 'The Treatment of Infant Diarrhea"

Dallas Health Museum—On September 17 at luncheon in the Baker Hotel the Dallas Health Museum was formally organized The project is one of the first adopted by the newly organized Dallas Academy of Medicine The Dallas Park Board has designated a building in Fair Park for the use of the Dallas Health Museum which will be considered a permanent Dallas institution It opened officially October 5 during the state fair of Texas with Dr Bruno Gebhard, director of the Cleveland Health Museum, as the principal speaker Mr R L Thomas has been named the first president of the Dallas Health Museum, Mr Charles R Moore and Mrs Margurite Hays as vice president Mr W Ray Spears as treasurer and Dr Milford O Rouse Dallas, as secretary

VIRGINIA

Portrait of Physician—An oil portrait of the late Dr William O Smith was recently presented to the Piedmont General Hospital, Altavista Dr Smith practiced in Pittsylvania County and Altavista for more than forty years, he died in 1940

Memorial to Dr. McCluer.—The McCluer Clinic is to be established in Alexandria under the auspices of the Virginia Cancer Foundation with Dr Herbert D Wolff Jr Alexandria, as director, newspapers reported October 9 The clinic will be a center for the diagnosis and treatment of cancer and will be a memorial to the late Dr John C McCluer, Parkersburg, who died in 1945 The memorial is being set up to honor Dr. McCluer who during his twelve years as director in Alexandria was a leader in the improvement of community health facilities

First Chief Medical Examiner.—Dr Herbert S Breyfogle, St Louis, has been appointed the first chief medical examiner in Virginia Dr Breyfogle will have direct supervision of the administration of an act of the 1946 general assembly which established an entirely new system of coroners' examinations and reports. Under the act the report is required from each local coroner on the circumstances of every death occurring in his county or city under unnatural or suspicious circumstances. Dr. Breyfogle graduated at the University of Chicago School of Medicine in 1937 and until his new appointment was director of the medicolegal department of St. Louis County, where he was also acting coroner.

Personal.—Drs. George H. Carr Jr., Portsmouth, and Guy W. Horsley, Richmond, are members of the state board of medical examiners for the second and third districts, respectively, succeeding Dr. Philip S. Moncure, Norfolk, and Dr. Hack U. Stephenson, Richmond, whose terms expired July 1. Dr. Moncure has served on the board continuously since June 1918 and Dr. Stephenson since December of the same year. The board adopted a resolution in appreciation of the work done by these two physicians.——Dr. James L. Hamner, Mannboro, has been appointed a member of the state board of health, effective July 1, succeeding Dr. John B. Jones, Petersburg, resigned.——Dr. Thomas B. Pope, Kingston, has been appointed coroner of the city of Petersburg to succeed Dr. Henry M. Snead, who recently resigned.

WISCONSIN

Fall Program Opens for Medical Society.—The first of the 1946-1947 series of meetings of the University of Wisconsin Medical School was held October 15 in Madison with a presentation by Dr. Harold P. Rusch, Madison, on "Research Projects at the McArdle Memorial Laboratory" and James A. Miller, Ph.D., Ann Arbor, and Elizabeth C. Miller, Ph.D., on "The Present Status of Research on the Hepatic Carcinogen p-Dimethylaminoazobenzene." All the speakers are members of the staff of the McArdle Memorial Laboratory at the university.

New Cancer Division.—The Wisconsin State Board of Health in August authorized the establishment of a new cancer division to intensify the crusade against cancer. A specially qualified physician will be sought as supervisor. The new department will cooperate with existing anti-cancer groups in the state, including the Field Army and the operating committee of the State Medical Society of Wisconsin. According to the Wisconsin State Board of Health Bulletin, cancer has claimed 92,062 lives in Wisconsin during the past twenty-six years, an average of more than 3,500 yearly. The disease has been the second leading cause of death since 1920.

Physicians Honored.—A public program was held in the Oconomowoc State Park, September 29, to honor Dr. Michael R. Wilkinson on the occasion of his eighty-second birthday. Dr. Wilkinson has been practicing in the city fifty-three years. He has held various offices in the Waukesha County Medical Society and is currently president of the Waukesha County Historical Society and athletic director of Oconomowoc High School. He has four sons who are physicians.——Dr. John M. Dodd, Sr., who has practiced in Ashland for fifty-six years, was entertained by the Odd Fellows, October 5, to celebrate his eightieth birthday.——Dr. W. H. Vosburgh, Denmark, was guest of honor recently at a public gathering honoring his fifty years' service to the community.

HAWAII

Personal.—Dr. Marcus Guensberg, formerly of New York, has been appointed medical director of the Territorial Hospital, Kaneohe, to succeed Dr. Ellis A. Stephens, who resigned to enter private practice.——Dr. and Mrs. (Dr. Tai Heong Kong) K. R. Li, Honolulu, celebrated their golden anniversary with an open house on July 14. This date also was the cause for celebration of fifty years of medical practice in Hawaii for each of the couple as well as their seventy-first birthdays.——Dr. Theresa Woo, formerly a captain in the medical corps of the army, was recently appointed pediatrician with the bureau of maternal and child health of the board of health. She succeeds Dr. Martha W. Groves, née Martha C. Wager, who resigned in June.

PUERTO RICO

Hospital Construction.—At a recent meeting held at the governor's palace in San Juan of representatives of the Insular Department of Health, the U. S. Public Health Service and the Planning Board, a general discussion of the hospital construction program for the next five years resulted in the creation of a committee to coordinate the work to be carried out in order that Puerto Rico might receive the benefits of the hospital construction program with federal aid. It is estimated that Puerto Rico will receive no less than $12,000,000 of federal aid for the construction of hospitals during the next five years. Governor Piñero has designated an advisory committee to prepare and execute the proposed program. Puerto Rico will contribute an amount of funds equal to that designated by the act of Congress. As a result of the large population of this island and the tremendous need for the construction of hospital facilities, as well as the reconstruction of existing facilities, the overall allocation of funds will be more than $25,000,000 for the next five years for both insular and federal funds. The Planning Board of Puerto Rico has adopted a master plan for the construction of district hospitals and also a preliminary master plan for municipal hospitals that will serve as a guide in the preparation of the whole program for the island.

GENERAL

Examinations in Otolaryngology.—The American Board of Otolaryngology will conduct examinations in 1947 at the Coronado Hotel, St. Louis, April 16-19, and Palmer House, Chicago, October 7-11.

Marriage and Family Health Education.—Janet F. Nelson, Ph.D., has been appointed director of marriage and family life education of the Planned Parenthood Federation of America. The service is new and will reach 350 local groups affiliated with the federation to develop services considered essential to the strengthening of the American family. Dr. Nelson has been serving as consultant on personal and family relationships from the U. S. O. division of the Y. W. C. A.

Urology Award. — The American Urological Association offers an annual award not to exceed $500 for an essay (or essays) on the result of some clinical or laboratory research in urology. Competition will be limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals. For full particulars write the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tenn. Essays must be in his hands before May 1, 1947. The selected essay (or essays) will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Hotel Statler, Buffalo, June 30-July 3, 1947.

Mayo Foundation Receives Pharmaceutical Award.—The Mayo Foundation for Medical Education and Research will be presented with the award of the American Pharmaceutical Manufacturers' Association at its meeting in New York, December 9. The award of distinction goes to the foundation in recognition of its great contributions to public health, by fundamental research in the field of medical sciences, for the profound and lasting benefit of mankind. Isaiah Bowman, LL.D., president, Johns Hopkins University, Baltimore, will make the presentation address and Dr. Donald C. Balfour, director, Mayo Foundation for Medical Education and Research, Minneapolis, the speech of acceptance. Speakers during the ceremony will be:

Dr. Louis Schwartz, Washington, D. C., Progress in Fungus Disease Therapy.
Dr. Andrew Yeomans, Baltimore, Progress in Rickettsial Disease Therapy.
Dr. Samuel M. Feinberg, Chicago, Progress in Allergy Therapy.
Dr. Edward H. Rynearson, Minneapolis, Progress in Hormone Therapy.
Dr. Chester S. Keefer, Boston, Progress in Antibiotic Therapy.

Changes in Status of Licensure.—The California State Board of Registration in Medicine announces the following:

Dr. Isaiah J. Waterman, Seal Beach, Calif., license restored August 6.
Dr. Lee E. Smith, Oakland, Calif., license restored August 5.
Dr. John Jerome Tobinski, Los Angeles, license restored August 5.
Dr. Eugene Curry Nelson, Los Angeles, license restored August 5.
Dr. Gottfried Karl Friedrich Schnarrenberger, Los Angeles, license suspended for six months, effective August 17.
Dr. William Everts Downing, Clovis, Calif., license suspended for one year, effective August 17.
Dr. James Arthur Moran, Carmel, Calif., license suspended for one year, effective August 17.
Dr. William T. Engleman, San Bernardino, Calif., license revoked August 6.

The New York State Board of Medical Examiners announces the following:

Dr. Maynard Smith Owen, New York, license suspended for one year, effective July 1.
Dr. Edward Parrish, New York, license suspended for six months, effective July 26.
Dr. Meyer Louis Alpert, New York, license revoked July 31.

Meeting of College of Surgeons.—The clinical congress of the American College of Surgeons will be held in Cleveland, December 16-20, under the presidency of Dr. William Edward Gallie, Toronto. Headquarters will be in the Cleveland Public Auditorium and the Statler and Cleveland hotels, with most of the sessions, except the clinics at the hospitals, being held in the auditorium. The first Martin Memorial Lecture will be a feature of the presidential meeting Monday evening with Dr. Edward D. Churchill, Boston, as the speaker on "The American Surgeon, Army of the United States." The lecture supplants the annual oration in surgery and is a memorial to both Dr Franklin H Martin and Mrs Martin. The founder of the college and of *Surgery Gynecology and Obstetrics* was joined by his wife in making the college the beneficiary at their deaths of the journal, together with its physical plant operated by the Surgical Publishing Company of Chicago of which they were the owners. Dr Martin died in 1935 and Mrs Martin in 1945. The program will include numerous scientific papers on various subjects symposiums on care of the patient before and after operation venous thrombosis and prevention of pulmonary embolism antibiotic and chemotherapeutic agents in surgery, orbital reconstruction including prosthesis the treatment of deafness, surgery of the nasal accessory sinuses, plastic surgery of the head and neck cancer, fractures and other traumas and advances from war experiences. There will also be a forum on fundamental surgical problems and various panel discussions. Dr Edwin W Ryerson Chicago, will deliver the Fracture Oration on "Modern Methods in the Treatment of Fractures" Wednesday evening.

Radiology Meeting—The thirty-second meeting of the Radiological Society of North America will be held at the Palmer House, Chicago, December 2 6, under the presidency of Dr Lowell S Goin Los Angeles who will speak on "Radiology and the Future" Other speakers will include

Dr Stanley S Nemec, St Louis *Differential Diagnosis of Retrocardiac Shadows*

Dr John D Camp Rochester Minn Calcification of the Cerebral Basal Ganglions and Its Roentgenologic Significance

E Dale Trout and Z J Atlee Chicago Filter Value Inherent in Very High Voltage Radiation Therapy Equipment

Anna Goldfeder D Sc New York Further Studies on the Relation Between Radiation Effects Cell Viability and Induced Resistance to Malignant Growth IV *Effects of Roentgen Rays on Mammary Tumors Autogenous to Inbred Strains of Mice (dbaB and C3H)*

Dr Sydney F Thomas Palo Alto Calif Appendiceal Coproliths

Dr Abraham E Rakoff Philadelphia, The Endocrine Factors in Pelvic Tumors with a *Discussion of the Papanicolaou Smear Method for Diagnosis*

There will be symposiums on carcinoma of the uterine fundus and cervix treatment and care of advanced cancer patients, diseases of the chest and x-ray diagnosis and therapy of bursitis and arthritis. The Carman Lecture will be delivered by Dr Robert N Newell professor of radiology Stanford University, San Francisco, on "Quality of Radiation in Therapy."

Narcotic Violations.—The Bureau of Narcotics of the U S *Treasury Department announces the following*

Dr Herbert A Wilson, McAlester, Okla, entered a plea of nolo contendere in the U S District Court at Ada to a violation of the Harrison Narcotic Law, on October 10 he received a suspended sentence of three years in the penitentiary and was placed on probation for a similar period, he was also fined $500.

Dr Glenn P Treadwell, Friendship, Wis pleaded nolo contendere in the U S District Court at Wausau to the Harrison Narcotic Law and also to the unlawful sending of poison through the mail. On May 15 he was sentenced to pay a fine of $750.

Dr Donald A Cowan, Sault Ste Marie, Mich pleaded guilty in the U S District Court at Detroit to violations of the Harrison Narcotic Law on April 24 he received a suspended sentence of two years in the penitentiary and was placed on probation for a period of four years.

Dr Robert G McMurray Marion Ohio pleaded guilty to the violation of the Federal Narcotic Law September 11, and was sentenced to a term of three years in the U S Public Health Service Hospital Lexington Ky.

Dr Thomas S Carter Miami Fla pleaded guilty in the U S District Court at Tampa to violation of the federal narcotic law and on September 6 was sentenced to a term of two and one half years.

Dr Claude L Shoemaker, Chicago pleaded nolo contendere in the U S District Court in Chicago to violation of the federal narcotic law and on September 25 was sentenced to a term of five years which was suspended and he was placed on probation for a period of five years.

Dr Charles F Johnson Kenton Ohio pleaded guilty in the U S District Court at Toledo Ohio to violation of the federal narcotic law and on September 18 was fined $1 000 and was placed on probation for a period of five years.

Dr Ernest M McKenzie Hollywood Road Hot Springs, Ark pleaded guilty in the U S District Court in Arkansas to a narcotic violation and on September [illegible] sentence was suspended and he was placed on probation for a period of two years.

Dr Augustus D Harper Crossville Ill pleaded guilty in the U S District Court at East St Louis Ill to violation of the federal narcotic law and on September [illegible] was fined $200 and placed on probation for a period of two years.

Research in Heart Diseases.—Eleven additional fellowships and three more grants in aid to medical institutions for research in diseases of the heart and of the arteries were announced September 25 by the Life Insurance Medical Research Fund, New York. The additional awards bring this year's allocation of research funds to nearly $700,000. Organized a year ago, the Life Insurance Medical Research Fund is supported by 149 legal reserve life insurance companies in the United States and Canada (The Journal, May 4, p 52). All research sponsored by the fund is devoted at present to the cardiovascular diseases. Applications for research fellowships for 1947 will close on Jan 1, 1947 and for grants-in aid on Jan 31, 1947. Fellowships range from $1 500 to $2 000 a year for junior fellows and from $2 500 to $3 500 for seniors. New recipients are *Harwell G Davis II, LL D*, Medical College of Alabama, Birmingham; Dr Charles V E Dowling, New York, at Western Reserve University, Cleveland; Dr Jerome Gross, New York, at Massachusetts Institute of Technology, Dr Harper K Hellems, Lewisburg, W Va, Peter Bent Brigham Hospital, Dr Jack L Lewis, Los Angeles, Stanford University; Dr Harold Mankin, Columbia University College of Physicians and Surgeons, Dr George E Murphy, Kansas City, Mo, Rockefeller Institute for Medical Research, and Dr Hugh Grant Skinner, New Toronto, Ont, Canada, University of Toronto. Three junior fellowships to students who have not yet completed their work for degrees in medicine or the medical sciences include Thomas C Hall, Boston, to work at Harvard Medical School, Boston, Miss Marie Louise Nieft, Chicago, to work at the University of Southern California School of Medicine, Los Angeles, and Murray Saffran, Montreal, Quebec, to work at McGill University. Grants-in-aid were awarded to the Carnegie Institution of Washington, D C, for support of research into the embryology of the veins of the brain under the supervision of Dr George W Corner, to McGill University for support of research toward the development of procedures for heart surgery under the supervision of Dr David W MacKenzie, and to New York University for support of research toward designing an extremely delicate sensitive apparatus for measuring the blood pressure in the heart under the supervision of Dr Homer W Smith. The fellowship awards bring the total number given by the fund in the first year of its operation to twenty, representing $55,800. The twenty fellows come from eleven states and two Canadian provinces and will engage in medical research at seventeen different institutions. Total funds expended for grants-in-aid amount to $633,591, for a total of fifty-five research projects.

PHILIPPINE ISLANDS

Medical Meetings Resumed—*In an editorial comment the Journal* of the Philippine Medical Association discusses the thirty-ninth meeting of the association, held May 7-11. *The thirty-eighth annual meeting was held in April 1941.* The editorial said that to ward off the obnoxious influences of the enemy and the possibility that the medical profession in this *country might be used toward ends inimical to the interests* of its inhabitants, the Philippine Medical Association suspended all its activities for the duration. One feature of the recent *meeting was the awarding posthumously for the first time in* the history of the association of a gold medal and a citation to Dr Candido M Africa, an innocent victim of the Japanese *atrocities, for his contributions to medical science.* The house of delegates formulated a program for the rehabilitation of the association and its component societies in order that they may *resume all their former activities, it adopted a resolution thank*ing the American Medical Association for its readiness to help in the rehabilitation of the Philippine Medical Association *and in the rebuilding of the medical library destroyed during* the war it approved the Principles of Medical Ethics of the Medical Profession in the Philippines and authorized the coun*cil to seek the approval of the secretary of health and public* welfare that these may be adopted officially by the board of medical examiners, and it expressed readiness in taking its *share of the burden of rehabilitating the devastated country.* Dr Januario Estrada was elected president. He was president of the Manila Medical Society and the Colegio Medico Farmaceutico de Filipinas *from 1941 until 1945.* He has been twice vice president of the Philippine Medical Association. Other officers include Drs Juan Z Santa Cruz and Gonzalo Santos, vice presidents, and Dr *Antonio S Fernando, secretary-*treasurer.

Marriages

Joseph S Thomas Jr Flushing N Y, to Miss Olive St Marie at Keene, N H September 12.

James Oscar Hall Jr, Erwin, Tenn, to Miss Emily Ruth Borden of Greeneville September 15.

Charles Thornton Cowart, Donalsonville, Ga, to Miss P *Eileen Holton of Atlanta recently*

L Ireland Magruder, Portsmouth, Va, to Miss Hattie Cridlin Taylor of Urbanna, July 29.

Thomas Marion Davis, Columbia, S C, to Miss Adelle Davis in Savannah Ga, August 31.

Roy L Robertson, Shreveport, La, to Miss Gloria Anne Nobles of Gibsland, June 1.

Edwin H Whitmarth to Miss Cecelia Dougherty, both of New Castle, Pa, July 3.

Deaths

Norval Harvey Pierce ⊕ Del Mar, Calif.; College of Physicians and Surgeons of Chicago, 1885; born in Washington, D. C., May 13, 1863; professor of laryngology, rhinology and otology emeritus at his alma mater, now known as the University of Illinois College of Medicine, where in 1915 he was appointed professor and head of the department; formerly professor of otology at the Chicago Polyclinic and the Chicago Post-Graduate School; specialist certified by the American Board of Otolaryngology; member of the Illinois State Medical Society, National Institute of Social Sciences, Chicago Historical Society and the Chicago Society of Medical History; chairman of the research committee on otosclerosis, Chicago Medico-Legal Society; fellow of the American College of Surgeons, Chicago Academy of Medicine and the Institute of Medicine of Chicago; member and past president of the American Laryngological Society, American Laryngological, Rhinological and Otological Society, American Otological Society and the Chicago Laryngological and Otological Society; surgeon in the U. S. Navy during the Spanish-American War; a major in the medical corps of the U. S. Army during World War I, serving at Camp Grant and as chief otolaryngology surgeon at the U. S. Army base hospital in Vichy, France; decorated with military honors for his work in plastic surgery; served on the staffs of the Illinois Eye and Ear Infirmary and St. Luke's Hospital in Chicago; died October 28, aged 83.

Henry Ewing Hale, Princeton, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; at one time on the faculty of his alma mater; formerly affiliated with the Vanderbilt Clinic and the Babies Hospital and attending physician at Bellevue Hospital in New York City, where for many years he served on the board of education; founder and an officer of the Princeton Historical Society; served on the Princeton township board of education; chairman of the New York Medical Advisory board in connection with Selective Service during World War I; died November 5, aged 77, of injuries received in an automobile accident.

Wilfred Anthony Rose, San Francisco; Tufts College Medical School, Boston, 1930; member of the American Medical Association and the Massachusetts Medical Society; interned at St. Luke's Hospital in Jacksonville, Fla., and the Wheeling Hospital in Wheeling, W. Va.; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Oct. 12, 1942; for fifteen months medical officer with a naval repair unit in the Pacific; released from active duty on Jan. 1, 1946; died September 24, aged 41, of coronary thrombosis.

Eva Colt Bagley, Sioux City, Iowa; Michigan College of Medicine and Surgery, Detroit, 1895; died September 25, aged 81, of carcinoma of the bladder.

Marshall Henry Bailey, Norwell, Mass.; College of Physicians and Surgeons, Baltimore, 1893; member of the American Medical Association; at one time medical adviser to the students of Harvard University in Cambridge; died September 18, aged 87.

Franklin Wetmore Blye, Chicago; University of Illinois College of Medicine, Chicago, 1926; member of the American Medical Association; served during World War I; died September 28, aged 48, of coronary thrombosis.

Henry Weston Brody, New York; Long Island College Hospital, Brooklyn, 1905; member of the American Medical Association; chief of the medical staff of the Greater New York Taxpayers Mutual Insurance Association; formerly on the staffs of the Gouverneur and Good Samaritan hospitals; died September 20, aged 66.

William Burke, Greenwich, Conn.; Long Island College Hospital, Brooklyn, 1896; on the staff of the Greenwich Hospital, where he died October 1, aged 76, of chronic nephritis.

Toussaint C. Cabana, Attleboro, Mass.; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1894; died August 15, aged 77, of mitral insufficiency.

Thomas William Cail, Newton, Mass.; College of Physicians and Surgeons, Boston, 1910; died July 29, aged 60, of carcinoma of the stomach.

Edwin Morey Chase, King City, Calif.; University of Southern California School of Medicine, Los Angeles, 1934; interned at Santa Fe Coast Lines Hospital in Los Angeles; served a residency at the Kern General Hospital in Bakersfield and on the staff of the Ventura County Hospital in Ventura; died in the Santa Clara County Hospital in San Jose, September 16, aged 43.

Eric Knox Collier ⊕ Tipton, Okla.; Tulane University of Louisiana School of Medicine, New Orleans, 1926; died in Norman August 9, aged 43.

Edward Martin Crane, Hardwick, Vt.; University of Vermont College of Medicine, Burlington, 1895; served during World War I; on the staff of the Hardwick Hospital; for many years chairman of the local school board; died in the Mary Fletcher Hospital, Burlington, September 4, aged 78.

Charles Herbert Dockstader ⊕ Massapequa, N. Y.; Bellevue Hospital Medical College, New York, 1891; an Affiliate Fellow of the American Medical Association; died August 19, aged 80, of chronic endocarditis.

Robert Rockwell Felter, Pearl River, N. Y.; University of the City of New York Medical Department, New York, 1894; member of the American Medical Association; served as president of the First National Bank and the board of education in Pearl River; died October 3, aged 89.

John Joseph Gossner, Fabius, N. Y.; Syracuse University College of Medicine, 1916; member of the American Medical Association; served as health officer for the past twenty-four years in charge of the consolidated health district of Fabius; school physician; member of the staff of the Crouse-Irving Hospital in Syracuse, where he died August 26, aged 55, of acute appendicitis with perforation.

James W. Grubbs, Bowling Green, Ky.; Kentucky School of Medicine, Louisville, 1893; died September 18, aged 83.

Isaac W. Hooper, Norman, Okla.; Baylor University College of Medicine, Dallas, 1904; died in the Municipal Hospital August 25, aged 79.

Walter William Hotchkiss, Jamestown, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; died August 17, aged 80, of carcinoma of the liver.

Frederic Clarke Jewett, Baltimore; Baltimore University School of Medicine, 1893; at one time professor of diseases of the nose and throat at his alma mater; died June 15, aged 78.

Howard Kahn, Baltimore; University of Maryland School of Medicine, Baltimore, 1900; at one time on the faculty of his alma mater; member of the American Medical Association; died in the Maryland General Hospital September 24, aged 68.

Edward John Kirwan, Ludington, Mich.; Rush Medical College, Chicago, 1897; on the staff of the Paulina Stearns Hospital; died September 19, aged 76, of cerebral hemorrhage.

Assadour Hagop Kludjian, Lowell, Mass.; Baltimore Medical College, 1894; died August 5, aged 77, of arteriosclerosis.

John Anthony Kropacek, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1912; member of the American Medical Association; formerly a member of the board of health in Cicero; died in the West Suburban Hospital, Oak Park, September 29, aged 58, of bronchopneumonia.

John Conrad Kunz, Cincinnati; Cincinnati College of Medicine and Surgery, 1891; member of the American Medical Association; on the staff of the Bethesda Hospital; died in the Christ Hospital September 18, aged 81, of aplastic anemia.

Margaret Rebekah Large, Lansdowne, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1909; died September 11, aged 70, of cerebral hemorrhage.

Michael Joseph Lawlor ⊕ Waterbury, Conn.; Columbia University College of Physicians and Surgeons, New York, 1906; for many years on the staff of St. Mary's Hospital; consulting surgeon at Hungerford Hospital in Torrington; died in a hospital at New London, N. H., September 16, aged 64, of ruptured abdominal aorta.

J. Joseph Link, St. Louis; Chicago Medical College, 1890; at one time on the staff of the City Hospital; died in St. Anthony Hospital July 31, aged 83, of carcinoma of the prostate.

Samuel Thomas B. McCabe ⊕ Johnsonburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1917; member of the staff of the Andrew Kaul Memorial Hospital, St. Marys; died in the Robert Packer Hospital, Sayre, September 10, aged 55, of dissecting aneurysm of the aorta.

John Denis McGowan, Sama Monica, Calif.; Harvard Medical School, Boston, 1885; fellow of the American College of Surgeons; at one time practiced in Chicago, where he was chief surgeon for the Commonwealth Edison Company; died September 10, aged 93.

Claude Worth McKee ⊕ Greensburg, Pa.; Rush Medical College, Chicago, 1897; served during World War I; member of the American Academy of Ophthalmology and Otolaryngology; for many years chairman of the advisory board of the Salvation Army; on the staff of the Westmoreland Hospital; died September 11, aged 70, of arteriosclerotic heart disease.

Bert Edward Mankopf ⊕ Washington, Mo.; Marion-Sims College of Medicine, St. Louis, 1897; served during World War I; captain, medical reserve corps, U. S. Army, not on active duty; died August 25, aged 72, of heart disease.

Oliver William Means Jr., Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1946; intern at the Hartford Hospital; died September 10, aged 31, of anterior poliomyelitis of the bulbar type.

John Burr Miller, San Antonio, Texas; Starling-Ohio Medical College, Columbus, 1910; member of the American Medical Association; formerly local physician and surgeon for the San Antonio and Aransas Pass Railroad; died June 11, aged 70, of brain tumor.

Edward Brent Mitchell, Lawton, Okla.; University of Louisville (Ky.) Medical Department, 1893; for many years affiliated with the Indian Service, serving as physician in charge of the eye, ear, nose and throat department of the Kiowa Indian Hospital; draft examiner during World War I; recently received recognition for his "faithful and loyal service" during World War II in the form of a selective service medal; for many years president of the Home Building and Loan Association; died August 13, aged 78.

Sheldon Alexander Morris, Jacksonville, Fla.; Medical Department of Tulane University of Louisiana, New Orleans, 1888; member of the American Medical Association; past president of the Duval County Medical Society; co-founder and president of the De Soto Sanatorium, now known as St. Vincent's Hospital; died September 12, aged 81, of bronchopneumonia.

William A. Moser, Grants Pass, Ore.; Medical College of Indiana, Indianapolis, 1903; died in August, aged 76.

Harry Clarke Moses, Prattsburg, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1908; served during World War I; killed August 30, aged 68, in an automobile accident.

Raymond William Paul ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1918; on the staffs of the Retreat for the Sick and the Stuart Circle Hospital; died in a local hospital September 22, aged 53, of hypertensive cardiorenal disease.

Harold Vincent Phelan ⊕ Cleveland; Georgetown University School of Medicine, Washington, D. C., 1921; specialist certified by the American Board of Ophthalmology; on the staff of St. Alexis Hospital; died in Shaker Heights September 1, aged 51, of coronary thrombosis.

Clarence Leighton Poley ⊕ The Dalles, Ore.; Northwestern University Medical School, Chicago, 1908; county health officer; on the staff of The Dalles Hospital, where he died August 8, aged 67, of cerebral hemorrhage.

Charles Marius Pomerat, Springfield, Mass.; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Que., Canada, 1894; died in the Brattleboro Retreat, Brattleboro, Vt., September 17, aged 83, of bronchopneumonia and cerebral arteriosclerosis.

Alfred Joseph Radgens, Detroit; Detroit College of Medicine, 1903, died in the Mount Carmel Mercy Hospital September 9, aged 67, of coronary thrombosis.

Charles Edward Ralph, Lansdowne, Pa.; George Washington University School of Medicine, Washington, D. C., 1915; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; formerly affiliated with the Veterans Administration; died September 12, aged 73.

Robert A. Range, Elizabethton, Tenn.; Kentucky School of Medicine, Louisville, 1898; died August 30, aged 72, of cerebral hemorrhage.

John Franklin Reeves ⊕ Bridgeton, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1911; member of the executive committee and past president of the Cumberland County Medical Society; served during World War I and on the examining board of the Selective Service during World War II; at one time served on the board of education; on the staff of the Bridgeton Hospital; died September 18, aged 60, of coronary thrombosis.

Daniel Edward Remsberg ⊕ Roanoke, Va.; University of Maryland School of Medicine, Baltimore, 1905; medical director of the Norfolk and Western Railway; died September 14, aged 72, of coronary occlusion.

Carl Martin Roan ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1908; fellow of the American College of Surgeons; served during World War I and as deputy coroner of Hennepin County; on the staff of the Deaconess Hospital; died September 11, aged 68.

Harry Lewis Rothblatt, Boston; Baltimore Medical College, 1908; died March 2, aged 61, of coronary thrombosis.

Joseph Napoleon Roy ⊕ Webster, Mass.; Baltimore University School of Medicine, 1902; died March 19, aged 74, of myocardial failure.

Philip Melbourne Schell, New York; Syracuse University College of Medicine, 1938; served an internship at the Hospital of the Good Shepherd in Syracuse and the Syracuse Memorial Hospital; a first lieutenant in the medical corps, Army of the United States, during World War II; died in the Columbus Hospital Sept. 17, 1945, aged 31.

Louis P. Schroeder, Addieville, Ill.; Hospital College of Medicine, Louisville, 1892; died September 13, aged 79.

J. Campbell Smith, Pasadena, Calif.; University of Maryland School of Medicine, Baltimore, 1885; member of the American Medical Association and the Missouri State Medical Association; formerly on the staffs of St. Luke's Hospital, St. Louis Skin and Cancer Hospital and the Evangelical Deaconess Hospital, all in St. Louis; died September 18, aged 86.

John De Forest Smith, Dayton, Ohio; Eclectic Medical Institute, Cincinnati, 1898; on the staff of the Miami Valley Hospital; died September 22, aged 74, of generalized lymphosarcoma.

John Hudson Storer, New York; New York Homeopathic Medical College and Hospital, New York, 1891; member of the American Medical Association; affiliated with the Community Hospital, where he died September 9, aged 80.

Ernest A. Spicker, Adams, Mass.; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, 1924; died March 27, aged 46, of trichinosis.

Charles Jewett Watson, Thomaston, Maine; Medical School of Maine, Portland, 1898; died in Dartmouth, Mass., June 30, of coronary thrombosis.

PUBLIC HEALTH SERVICE

Leslie Leon Lumsden ⊕ medical director, U. S. Public Health Service, retired, New Orleans; born in Granite Springs, Va., June 14, 1875; University of Virginia Department of Medicine, Charlottesville, 1894; did graduate work at Johns Hopkins University, Baltimore, 1894-1895; commissioned assistant surgeon in the U. S. Public Health Service in 1898; and assigned to New Orleans to assist in handling yellow fever epidemics; credited with being one of the first to suggest that yellow fever was transmitted by insects; served in California during the first outbreak of bubonic plague reported in the United States at the turn of the century, then was assigned to the Hygienic Laboratory, Washington, D. C., now the National Institute of Health, because of the prevalence of typhoid in the District of Columbia; continued his investigations of typhoid in many parts of the country; at Yakima, Wash., organized the first full time county health department in the United States; made house to house sanitary surveys in eighteen counties of sixteen states; became a passed assistant surgeon in 1903, surgeon in 1912, senior surgeon in 1928 and became medical director in 1930, serving until 1939, when he retired; member of the American Public Health Service; district director and research worker in New Orleans from 1931 to 1939; associated with the Tennessee Department of Public Health from 1939 to 1941; since 1943 lecturer in epidemiology at the University of Texas Medical Branch in Galveston; during World War I was assistant surgeon general in the U. S. Public Health Service; author of various U. S. Public Health Service publications on typhoid, rural sanitation, rural health work, tuberculosis and poliomyelitis; died in the U. S. Marine Hospital November 8, aged 71, of leukemia and pneumonia.

(*From Our Regular Correspondent*)

Nov. 2, 1946.

The Morale of the Soldier

At the Royal Society of Medicine was witnessed the unusual occurrence of a lecture on a medical subject by Field Marshal Montgomery, who delivered the Lloyd Roberts lecture, on the morale of the soldier. High morale, he said, was a quality without which no war could be won, and it should interest the medical profession because it was a mental product. As a citizen he would reflect the national character, which was therefore of great importance, and anything that weakened this weakened the army. In war the moral stature of some men would increase. Others, under the stress of battle, surrendered to fear and to fatigue and allowed their characters to disintegrate. Morale was a mental quality which maintains human dignity and develops latent heroism. High morale drew a man forward against his own desires. It is not toughness, though tough men may occasionally perform high acts of bravery. Four basic factors are essential to high morale: leadership, discipline, comradeship and self respect. Good morale is impossible without good leaders; all men are frightened at some time or other to a greater or less extent, and in fear men band together and look for guidance. At such moments they are not capable of standing alone: they find the burden too great. The leader accepts the burdens of others and earns their gratitude thereby and the right to lead them. The quality men recognize in their leader is decision. Fear makes a man sluggish and indecisive. The leader's power over his men is based on his ability to cut through that fear paralysis and to help others to escape from it. His greatest asset is his ability to act normally in abnormal circumstances and to think rationally when his men have ceased to think.

The object of discipline is the conquest of fear. The basis of fear is the awareness of danger, which comes when a man thinks that he is opposed by something more powerful than himself. Discipline helps him to lose his own identity and create a corporate sense. It also implies a conception of duty; but Montgomery thought that this did not embrace abstractions such as freedom, democracy, empire. A man's sense of duty extended to the friends around him.

This brought Montgomery to his third factor, comradeship. Morale cannot be good unless men come to have affection for one another. Comradeship is the great antidote to fear. Self respect, his fourth factor, develops if the other three are present. A powerful contributory factor to morale is success; it is not possible to maintain morale during a long period of defeat.

Finally the field marshal returned to his theme that the soldier is first of all a citizen. Nothing weakened a man more than trouble at home. The soldier had to have good living conditions and always good food, but there is a danger of considering welfare as an end. It will never produce high morale by itself because it is essentially soft. Hardness and privation are the school of a good soldier, idleness and luxury his enemies. It was not for nothing that one of the great rallying calls of the British had been the cry "Blood, toil, tears and sweat."

Research on Rheumatism

As far back as 1922 the Ministry of Health conducted a sample survey of insured workers to determine the incidence of the complaints commonly called rheumatism. It was found that these were responsible for a sixth of the cost of illness, and later a higher estimate was made. In 1945 the Medical Advisory Committee of the Ministry of Health recommended that diagnostic and research centers should be established for the study of chronic rheumatism and improvement in diagnosis and treatment. These centers were to be located in university medical schools and teaching hospitals. The Nuffield Foundation has made a grant of $400,000 spread over ten years toward establishing a center at the University of Manchester. This will be in the teaching hospital of the university, the Royal Infirmary, and will deal with short-stay inpatients and outpatients, who will be referred from outlying clinics in the region. For long-stay inpatients there will be a clinic at a base hospital near the center and a second base hospital in the country. At the base hospitals lengthy investigations will be carried out and problems of rehabilitation studied. The scheme will insure access to a large number of cases, especially in the early stages, which are considered requisite for a successful attack on the causation, diagnosis and treatment. At the center the work will cover two main fields: the clinical, sociologic and industrial aspects of the disease, and the fundamental study of the disease by pathologic, bacteriologic and biochemical methods. The clinical study will be under the direction of a physician who will have the cooperation of the orthopedic, physical therapy and dental departments of the university. The social aspects of the disease will be studied in cooperation with the University Department of Industrial Health. Pathologic conditions of bones and joints will be investigated under the direction of a pathologist expert in the subject. An important object is the diffusion throughout the health services of the area of knowledge gained at the university center and the bringing of physicians in the outlying area into closer relation with the medical school.

Revision of the International List of the Causes of Death

The registrar general of births, deaths and marriages announces that in connection with the revision in 1948 of the International List of Causes of Death the minister of health has appointed an advisory committee to consider from a medical point of view and to advise on the alterations to be suggested by the government. A number of physicians have been appointed to the advisory committee, including Dr. A. Bradford Hill, professor of medical statistics, London University, and Dr. Percy Stocks, medical statistician of the General Register Office. Recognition of the importance to medical research of internationally comparable statistics of causes of death inspired the formulation of the present classification, which was adopted by the International Institute of Statistics in 1893 and which has been revised on five occasions by an international conference convened decennially since 1900 by the French government. The main achievements of the conference have been the revision of the International List of the Causes of Death in accordance with scientific advances and initiation of the agreement relating to statistics of the causes of death signed in 1934 on behalf of twenty governments, which undertook to compile and publish their statistics according to the agreed International List. Provision has now been made for the next revision in 1948 and the establishment of an international nomenclature of diseases to be carried out under the auspices of the World Health Organization.

A National Radium Center

The government has decided to establish a national center for the processing and distribution of radium, radon and artificial radioactive substances required for scientific, medical and industrial purposes. The center will be operated by a private company, Thorium Limited, acting as agents for the Ministry of Supply. As a first step the ministry will purchase the radiochemical business owned by Thorium Limited, excepting the manufacture of luminous compounds and other secondary industrial products. The extraction of radon, which was carried on during the war under the supervision of the Medical Research Council, will be transferred to the new center. The work there will be closely coordinated with the ministry's activities in the field of atomic energy. It will be controlled by a council which will include representatives of the ministry, of the managing agent and of users of its products.

Centenary of the Academy of Surgery

On Aug. 25, 1843 seventeen young surgeons of the Paris hospitals, under the presidency of Auguste Berard, created the Society of Surgery, which became later on the Academy of Surgery of France. The centenary of the academy, postponed in 1943 on account of the Nazi occupation, was celebrated on the 9th of October under the presidency of Professor Basset at the Paris Town Hall. Dr. Louis Bazy outlined the history of this society of scientists. Among the representatives of foreign societies of surgery who brought messages were Dr. Mayer, representing the International Society of Surgery, Professor Petitclerc from Canada, Professor Whipple from the United States, Sir Max Page of the Royal College of Surgeons, Mr. James Graham, Professor Learmonth from England, Professor Gruca from Poland, Professor Girasek from Czechoslovakia and Professor Bengolea from Argentina. On behalf of the Paris municipality, Dr. P. Rouques drew up a plan for the reform of the Paris hospital system: reconstruction and enlargement of hospitals, one emergency center with powerful means of action, a corps of anesthetists, a special school for surgeons, institution of better living conditions and old age insurance for doctors.

Kinodensigraphy, a Method for Registering Invisible Pulsation of the Pulmonary Parenchyma

At a meeting of the Society of the Paris Hospitals, Professor Kourilsky presented a new method of exploration of a physiopathologic field, yet unpublished, evolved by Maurice Marchal for registering radiologic variations up to now invisible. The patient has the x-ray bulb at the back; a special radioelectric cell is placed at a distance from the thoracic wall. The x-ray beam is strongly diaphragmed, so that only a split beam of light can pass through it. By this method and by employing simultaneously several radioelectric cells, the measuring of the rapidity of circulation in a pulmonary arteriole, as well as the duration of the passage of the blood from the arterial level to the venous level of the lung, is possible. Kinodensigraphy can be used for diagnosis and for therapeutic control in all pulmonary diseases as well as in those of the heart and the blood vessels.

A New Medical Review

A new international review of psychoanalysis and of human sciences has been issued under the title of *Psyché*. It is published under the patronage of Prince Louis de Broglie, perpetual secretary to the Academy of Science, of Dr. Toulouse, president of the Mental Hygiene League, and of other personalities of the medical world; the director is Maxim Clouzet. In the first issue, among other contributions, are to be found articles by Dr. René Laforgue on psychoanalytic sociology, Dr. Gisèle Galy on twenty-five years of French medical hygiene and Dr. Juliette Boutonier on the crisis of adolescence.

Miscellaneous

The Academy of Surgery has commemorated the death of Dr. Howard Lilienthal of New York, a foreign associate member. During the first world war he conducted in France a specialized unit organized by the Mount Sinai Hospital. The academy has also commemorated the death of Professor P. N. Hansen of Copenhagen, a foreign associate member.

Professor Louis Bugnard, professor of biology at the Toulouse Faculty of Medicine, has been appointed director of the National Institute of Hygiene in the place of Professor A. Chevallier, retired.

The first chairmanships of labor medicine have been created at the Faculties of Paris, Lyons and Lille.

ITALY

(From Our Regular Correspondent)

Naples, Oct. 1, 1946.

The Price of Drugs

During the last few months the Italian market has become seriously overloaded with American drugs. Large quantities of hormones, vitamins and tonics have been mailed from relatives in the United States to some people here in order to make a profitable business. All these drugs remain now unsold in the private homes of these people. They are far too expensive; furthermore, there is an abundance of Italian drugs. The only well known American drugs for which substitutes are not available at present are folic acid, penicillin and streptomycin. Folic acid costs 200 lire per tablet. Two hundred thousand units of penicillin may be obtained for 1,500 lire (six months ago the price was 8,000 lire). The price of streptomycin is 25,000 lire per gram. French and Swiss firms which have their own branches in northern Italy are now competing with the expensive American drugs by selling their products for the same price as the Italian drugs.

Meeting of Radiologists

At a convention held September 21-23 the radiologists of Italy were encouraged to learn of the fluoroscopic station in New York, where in the course of a few days chest examinations of three million of the population were carried out for diagnostic purposes. A fluoroscopic station, not exactly like New York's but modern and very active, is that of Milan, where it is reported that latent tuberculosis was found in 2 to 3 per cent of 100,000 persons examined in a few days; this is considered a very low percentage. Vice versa, 50 per cent of latent forms were demonstrated on fluoroscopy in the antiaircraft corps, where in wartime there was an influx of all those who had been rejected from the army and from the navy for physical deficiency. Among other subjects discussed at this meeting were angina, melanoblastoma, carcinoma, lupus and tomographic studies of tumors of the lungs and of dense para-aortic shadows. The chairman was Professor Vallenbona, who is considered in Italy to be the inventor of the tomographic method.

BELGIUM

Sept. 27, 1946.

Medical Supervision of Schools in the Congo

A plan is taking shape which is truly beneficial from the point of view both of hygiene in general and particularly of the health of our colonial pupils. From now on all the educational establishments of the Belgian Congo and of its annexed territories of Ruanda-Urundi are to be subject to regular medical inspection. This service is assigned to the physicians of the government and to those who are approved by the governor of each province or by the governor of Ruanda-Urundi. In the schools for Europeans the students are examined at the beginning of the school term. Those whose state of health requires special supervision or who are especially designated by the master of the school or by other members of the teaching staff are reexamined by the medical inspector. The premises likewise are the object of annual inspection. The doctors in charge of these investigations have the right to order measures to be taken if contagious diseases arise. They must make sure that a medical record is kept of each student, they are to exercise medical control over sports, and in the boarding houses and boarding schools they are to supervise the diet. In the schools for the natives, the medical inspectors likewise proceed with the annual examination not only of the pupils but also of the buildings, annexes and furnishings. The keeping of the medical record cards for each individual must be a rule in large groups. The diet and sports likewise should not escape medical inspection.

Correspondence

"THE HELPING HAND," BY EMILE RENOUF

To the Editor:—It is rather out of the ordinary to have ditorial comment on an advertisement in THE JOURNAL, but Iead Johnson and Company in their advertisement in the issue f October 5 reproduced a picture that to my mind is out of he ordinary. Since 1902, when at the age of 10 years I began o be a frequent visitor to the Corcoran Art Gallery in Washngton, I have been very fond of a painting called The Helping Iand, by Emile Renouf, painted in 1881. Renouf, the cenennial of whose birth was June 23, 1945, spent his life in his ative Honfleur, across the river from Havre, and the grandather and grand-daughter in this picture are fishing folk of that egion. The painting has its own story to tell. What I should ike to call to the attention of any who may enjoy this excellent rint is that the Corcoran Gallery's having the painting in the irst place is a monument to the integrity of George Ingraham Seney, a Brooklyn banker whose name is linked with the Iethodist Hospital of Brooklyn, of which he was a heavy beneactor. Part of the story is told in Appleton's Dictionary of merican Biography. He got into financial straits over some ailroad financing in the early eighties which went bad, and to rotect the depositors in his bank against loss he put up his nansion and his art collection at auction. The latter, with a ook value of $500,000, brought a little more than $400,000 at forced sale. The Corcoran Gallery bought Renouf's painting t this sale for $7,600. With the money realized from the sale f the house and the pictures, Seney paid off his depositors in ull. The Helping Hand has brought pleasure to innumerable isitors to the Corcoran Gallery who do not have knowledge of he story back of it. It adds to my enjoyment of it to know hat a man who valued his integrity above money owned it and arted with it. It seems opportune in an opportunist age to nake this bit of history available to the public.

RAMSAY SPILLMAN, M.D., New York.

ENURESIS

To the Editor:—I have read with considerable interest the article on "Enuresis, a Psychologic Problem of Childhood," by Dr. Clifford Sweet in THE JOURNAL, October 5. I am in agreement with Dr. Sweet's concept of the condition and with his recommendations for treatment. The treatment he recommends includes (1) examinations for organic disease or defect and their correction, if any are found (such defects are probably present in only a small percentage of cases of enuresis) and (2) psychotherapy, which, as stated by Dr. Sweet, consists in "reeducation of the parents and the child rather than the use of any drug, change in diet or fluid intake or any surgical instrument."

There is, however, a specific form of psychotherapy which I should like to recommend. It should probably be referred to as a psychoneuromuscular exercise. It is very simple and succeeds only in the case of children who are old enough to cooperate. This includes all who are over 6 years of age and even some who are younger.

The child is instructed to stop and start the flow of urine two or three times during each daytime micturition. This procedure exercises the psychoneuromuscular mechanism as a whole and helps to establish the dominance of the higher psychic centers over the purely reflex neuromuscular mechanism. The cerebral dominance which is established soon carries over into the unconscious period of sleep. In the case of small children, it is well for one of the parents to stand by during daytime micturition and coach the child in the exercise of starting and stopping the flow.

As a full time pathologist I have not had the opportunity to recommend this exercise directly to patients. However, I know of several cures obtained by physicians who at one time or another have consulted me regarding their enuresis problems. Many children will be cured in one to three weeks' time by the faithful performance of the exercise recommended. One woman about 20 years of age had postponed her marriage several times because of enuresis. She rapidly cured herself by the foregoing psychoneurosphincter exercise.

I have wanted to report this simple treatment for several years but have hesitated to do so because I have not collected documented case histories.

EDWIN E. ZIEGLER, M.D., Lancaster, Pa.

AFTER-CARE OF CORNEAL FOREIGN BODIES

To the Editor:—In the New York Navy Yard, where 70,000 civilians were employed, 52,704 injuries were reported in 1944. Of these, 11,380, or 21 per cent, were accidents to the eye, predominantly caused by the presence of foreign bodies.

While the foreign bodies in the conjunctiva were readily removed without loss of time on the part of the employees, those in the cornea, particularly the metallic bodies with a circumscribed rust ring, were not as easily taken out and usually gave rise to absenteeism. These lost man hours were due chiefly to the fact that the eye was covered after removal of the particle, with a consequent loss of binocular vision. As this incurred an added hazard to an already hazardous job, the patients frequently were permitted to go home or were transferred temporarily to an unskilled nonhazardous position. Ocular pain, too, was a definite contributing cause of time lost.

Following the removal of an embedded foreign body in the cornea, it is unnecessary to put a patch over the eye even in an atmosphere where foreign bodies abound. This observation is based on the treatment of several hundred cases. No apparent retardation of healing was noted in comparing a group of this type with an identical series of patients whose eyes were occluded.

At the Navy Yard, after an embedded corneal foreign body was removed, a small amount of ocular anesthetic ointment, butyn sulfate 2 per cent, was placed in the lower cul-de-sac, and the eye was left uncovered to preserve binocular vision. A systemic anodyne, such as 15 grains (1 Gm.) of acetylsalicylic acid, was given orally. In order for the patient to continue his work in comfort, the local application was repeated at least once or twice during his working hours. For this purpose he was supplied with a limited amount of the analgesic, the commercial tube of ⅛ ounce of ointment being an excessive quantity. A gelatin capsule of O size, holding one sixth of the contents in the tube, provided an ample amount to insure the patient against discomfort for the ensuing twelve hours. Such a capsule proved satisfactory and contained sufficient salve for four treatments. Each patient was also given another 15 grains of acetylsalicylic acid, which he was instructed to take for the prevention of subsequent pain.

Considering the many establishments where conservation of working time is desirable, this plan of treatment recommends itself since it affords adequate therapy, reasonably administered, and is consistent with good results.

ARTHUR A. KNAPP, M.D., New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Hospitals: Liability for Negligence of Nurse and Intern in Giving Blood Transfusion to Wrong Person.—The plaintiff sued for damages for personal injuries resulting from the alleged negligence of the defendant in the administration of its hospital. From a judgment for the plaintiff the defendant appealed to the supreme court, appellate division, fourth department, New York.

The plaintiff entered the defendant's hospital on advice of her physician and was assigned as a paying patient to a private room. After undergoing an operation she recovered to the point where it was anticipated by her and her physician that she would leave the hospital forty-eight hours later. Prior to her leaving, an intern and a nurse entered her room and informed her that she was to have a blood transfusion. The plaintiff asked who the donor was to be and, on being informed by the nurse that it was to be her daughter, the plaintiff replied "I haven't got a daughter." The nurse and intern, however, went ahead and started the transfusion. During its course the plaintiff had a chill and a rising temperature and the transfusion was stopped and her physician summoned. The plaintiff suffered severe headaches and in later days became mentally ill and spent some time in a state hospital for the insane. At the time of the transfusion she was at, or approaching, her menopause, and the transfusion was the turning point that caused her subsequent illness and suffering.

Blood transfusions at the hospital were ordered only by a patient's attending physician or by a house physician. In this case one of the physicians in the hospital, Dr. James S. Houck, following the usual practice, left at the office of the hospital a filled out form directing the giving of a blood transfusion to one of his patients, a woman on the same floor of the hospital as the plaintiff. In due course of time the form with its directions and the blood to be used were given to the intern and the nurse. Through some mistake the intern and the nurse entered the plaintiff's room and gave her the transfusion.

The question here involved, said the court, is whether or not the defendant, a charitable hospital, is liable in damages to the plaintiff, a paying patient, for injuries due to the mistake of an intern attached to the defendant hospital. Historically the courts have been chary to fix liability on charitable hospitals, especially for torts to patients. Originally there was a theory that a patient entering a charitable hospital, owing to the very nature of its eleemosynary work, waives any claim for damage resulting to the patient in the hospital. This theory is not now extant in New York, at least with reference to paying patients. Liability can be placed on a charitable hospital for damage to a patient from the negligent performance of an administrative or ministerial act on the part of an employee, but it is very substantially established in the law of this state that a hospital is not liable for a tort committed on a patient by a physician, nurse or other employee in his or her performance of professional duties, provided the hospital has exercised due care in the selection of properly qualified professional staff. If the hospital joins in a tort perpetrated by a professional member of its staff, however, or could have prevented such tort in the exercise of proper supervision of occurrences in the hospital, then there might be liability on the part of the hospital to the person injured.

Received and kept as a patient at the hospital, the plaintiff in this case was entitled to be protected by the hospital and its employees against trespass, assault and negligence if such trespass, assault or negligence could be reasonably anticipated by the hospital. If the nurse-intern team had given the transfusion to the proper patient, they were doing it in the place of her physician and in so doing would not act in any respect on behalf of, or for, the hospital. No matter how seriously they would have erred in giving the transfusion to the proper patient, if they had done so they could not cause liability on the hospital by such error. But the transfusion was not given to the proper patient but to the plaintiff. What happened here was at least negligence on the part of the hospital's employees, if not trespass and assault. To avoid such negligence or act of misconduct would be the duty of the hospital, and yet here such negligence and misconduct were committed by the very persons whom the hospital employed for certain duties and thus gave access to the rooms and persons of patients. Their entrance into the wrong room caused the professional nature of their errand to cease. As employees of the hospital they, among other employees, had placed on them the duty of protecting patients. After notice was given to them by the plaintiff that she was not the patient for whom the transfusion was intended, they, as servants of the hospital, should have ceased in their effort to give the transfusion and should have protected her from the torts inflicted on her. In their failure to perform this duty, they did not act as professional persons, and there is no reason why their failure should not cast liability on the hospital. The judgment in favor of the plaintiff was affirmed.—*Necolayff v. Genesee Hospital, 61 N. Y. S. (2d) 832 (N. Y., 1946).*

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in The Journal, Nov. 23, page 734.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, Jan. 21-23. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

Delaware: *Examination.* Dover, Jan. 14-16. *Endorsement.* Dover, Jan. 21. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia: * *Reciprocity.* Washington, Dec. 9. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Kansas: Kansas City, Dec. 4-5. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 16-18. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maryland: *Examination.* Baltimore, Dec. 10-13. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore 1. *Homeopathic.* Baltimore, Dec. 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Michigan: * Ann Arbor, Dec. 9-11. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota: * Minneapolis, Jan. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowery Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, Dec. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Nebraska: * *Examination.* Omaha, June 1947. Dir., Bureau of Examining Board, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

New Hampshire: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

North Carolina: *Examination.* Winston-Salem, Dec. 16-19 postponed. *Endorsement.* Raleigh, Jan. 16. Act. Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, Dec. 3-5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma: * *Reciprocity.* Oklahoma City, Dec. 29-30. Sec., Dr. J. D. Osborn Jr., Frederick.

South Dakota: * *Examination and Reciprocity.* Vermillion, Jan. 21-22. Sec., Dr. Gilbert Cottam, State Capitol Bldg., Pierre.

Tennessee: * Memphis, Dec. 18-19. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.

Utah: Salt Lake City, Dec. 18-20. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City 1.

Vermont: *Examination.* Burlington, Jan. 31-Feb. 1. Sec., Board of Medical Registration, Dr. F. J. Lawliss, Richford.

Virginia: Richmond, Dec. 3-6. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

Washington: *Examination.* Seattle, January 1947. Sec., Mr. Nelson Vaughn, Olympia.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Dec. 10. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: Denver, Dec. 11-12. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Iowa: Des Moines, Jan. 14. Corresponding Sec., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

South Dakota: Sioux Falls, Dec. 6-7. Sec., Dr. G. M. Evans, Yankton.

Tennessee: Memphis and Nashville, Dec. 19-20. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis 3.

Wisconsin: Milwaukee, Dec. 7. Sec., Professor Robert N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

Precordial Electrocardiogram in High Lateral Myocardial Infarction. F. F. Rosenbaum, F. N. Wilson and F. D. Johnston.—p. 135.

*Demonstration of Ventricular Septal Defect by Means of Right Heart Catheterization. Eleanor deF. Baldwin, Lucille V. Moore and R. P. Noble.—p. 152.

Simplified and More Standardized Technic for Recording Multiple Precordial Electrocardiograms. A. J. Geiger and Jessamine R. Goerner.—p. 163.

Influence of Variations in Atmospheric Temperature and Humidity on Rates of Water and Heat Loss from the Respiratory Tract of Patients with Congestive Heart Failure Living in a Subtropical Climate. G. E. Burch.—p. 190.

Effect of Meals on Electrocardiogram in Normal Subjects. E. Simonson, A. Henschel and A. Keys.—p. 202.

Velocity of Blood Flow in Normal Pregnant Women. B. Manchester and S. D. Loube.—p. 215.

Acute Pericarditis in Young Adults. R. M. Nay and N. H. Boyer.—p. 222.

*Incidence of Rheumatic Fever and Heart Disease in School Children in Dublin, Ga., with Some Epidemiologic and Sociologic Observations. R. W. Quinn.—p. 234.

*Anomalous Origin of Left Coronary Artery from Pulmonary Artery: Report of Case Diagnosed Clinically and Confirmed by Necropsy. S. Eidlow and Eleanor R. Mackenzie.—p. 243.

Catheterization of Right Side of Heart.—According to Baldwin and her co-workers clinical diagnosis of isolated ventricular defects has been entirely dependent on the presence of the pathognomonic Roger murmur, a localized loud blowing systolic murmur heard best just to the left of the midsternum and often accompanied with a palpable thrill. Since the shunt is arteriovenous, cyanosis is not present except rarely as a terminal manifestation. Many ventricular septal defects are not recognized during life but are found only at necropsy. The development of a technic for the catheterization of the right side of the heart in man presents a new diagnostic aid for the detection of this congenital defect. Following the introduction of a catheter into the right side of the heart, samples of blood may be withdrawn from various areas by determining the position of the tip of the catheter by fluoroscopy. The presence of an arteriovenous shunt may then be demonstrated by the comparison of the respiratory gas contents of these blood samples with one another and with samples of arterial blood. Further information on the hemodynamics may be obtained by connecting the intracardiac catheter to a recording type of manometer, such as the one described by Hamilton, and analyzing the resultant pressure tracings. By direct observation of the movements of the catheter within the right side of the heart, impressions as to the size, shape and location of the chambers of the heart may be acquired which supplement the information obtained from the routine x-ray and fluoroscopic studies. The authors report observations made by means of right heart catheterization on the hemodynamics of two subjects with congestive failure of obscure etiology. In both subjects a large ventricular septal defect was demonstrated by the arterialization of the right ventricular blood.

Rheumatic Fever and Heart Disease in School Children.—Dublin, Ga., the site of the U. S. Naval Hospital for Rheumatic Fever, seemed well suited for a survey of heart disease in school children, since it is located in one of the Southern states at a latitude of 32.5 degrees and a longitude of 83 degrees. The elevation is 234 feet. The annual rainfall is approximately 50 inches. A cardiac survey of 401 school children in the fifth, sixth, seventh and eighth grades revealed 6 cases of organic heart disease, giving an incidence of 1.5 per cent. Of these, 4 had rheumatic heart disease and 2 had congenital heart disease. The incidence of rheumatic heart disease was found to be 1 per cent for all children examined, 1.26 per cent for white children and 0.60 per cent for Negro children. The incidence of congenital heart disease was 0.5 per cent. The incidence of rheumatic fever was 2 per cent. The incidence in white children was 2.10 per cent and in Negro children 0.60 per cent. Climatologic and socioeconomic factors such as dampness, crowding, inadequate housing, malnutrition and low economic status, which are very important epidemiologically in rheumatic fever and rheumatic heart disease, were found to exist in Dublin, Ga.

Anomalous Origin of Left Coronary Artery.—Eidlow and Mackenzie give the history of a female infant who was born in February 1945 and died in June of the same year. The anomalous origin of the left coronary artery from the pulmonary artery was diagnosed during life. The observations on which the diagnosis was made were paroxysms of cardiac pain characterized by sweating, pallor, cyanosis and dyspnea, great enlargement of the heart both clinically and by x-ray examination, and electrocardiograms showing inversion of T waves in leads 1 and 2. These constitute a syndrome indicating inadequate arterial blood supply to the heart muscle. The clinical diagnosis was confirmed by necropsy, which revealed a left coronary artery arising from the pulmonary artery and supplying the left ventricle alone. No anastomotic coronary circulation existed. Pulmonary atelectasis, a feature of this case, has been recorded in other cases and is probably secondary to the hypertrophy and dilatation of the heart. Consistent with the majority of cases reported, this patient appeared normal at birth. There is no adequate explanation for the absence of symptoms during the early weeks of life. One may speculate that the blood supply to the myocardium may be adequate when activity is at a minimum. Another explanation suggested is that a slight patency of the ductus arteriosus, which may have escaped occlusion in the early weeks of life, permits a mixture of arterial with venous blood in the pulmonary artery.

Fractures in Long Bones of Infants with Subdural Hematoma.—Caffey reports 6 cases in which there were 23 fractures and 4 contusions of the long bones. In not a single case was there a history of injury to which the skeletal lesions could reasonably be attributed, and in no case was there clinical or radiologic evidence of generalized or localized skeletal disease which would predispose to pathologic fractures. It is possible that some of the fractures in the long bones were caused by the same traumatic forces which were presumably responsible for the subdural hematomas. This did not happen in the majority of the fractures, because 17 fresh fractures appeared many weeks and months after the first clinical manifestations of subdural hematoma and after the withdrawal of bloody fluid from the subdural space. In 1 case fractures in the long bones developed six months after the subdural tumor had been removed surgically. The author also considered the possibility that the long bones were injured and fractured during convulsive seizures. There is little evidence to support such a postulate. The author concludes that the presence of unexplained fractures in the long bones warrants investigation for subdural hematoma. Routine x-ray examination of the long bones in subdural hematoma is necessary for the identification of fractures, because many of them are silent clinically.

Prolonged Hepatitis and Cholangiolitic Cirrhosis.—Watson and Hoffbauer report 8 cases of cholangiolitic hepatitis. Certain cases of prolonged hepatitis exhibit normal or relatively normal hepatocellular function in the presence of regurgitation jaundice. The histologic changes often appear inadequate to account for the jaundice. These consist of a varying amount of periportal lymphocytic infiltration, bilirubin staining of the liver cells, especially in the centers of the lobules, and bile thrombi. In the absence of sufficient evidence of this type to indicate intrahepatic biliary obstruction, it is believed that the continued regurgitation of bile supports the concept of increased permeability of the cholangioles. This regurgitation is manifested by hyperbilirubinemia, hypercholesterolemia, hyperphosphatasemia and pruritus. In some cases of epidemic hepatitis liver biopsy may fail to reveal appreciable hepatocellular injury when infectious activity is still manifest. Since in these cases there is often residual evidence of reduced hepatocellular function, it is believed that initially there was a more severe liver cell injury and that the prolonged regurgitation jaundice indicates more severe damage of the intrahepatic bile duct system than in the ordinary case. The authors suggest that the term cholangiolitic cirrhosis is more appropriate and distinctive than hypertrophic biliary cirrhosis. Regurgitation jaundice without ascites, but with pruritus, hypercholesterolemia and hyperphosphatasemia are prominent in this group of cases. The final stages of cholangiolitic cirrhosis following prolonged hepatitis may be indistinguishable anatomically from ordinary atrophic or portal cirrhosis. The cholangiolitic type of hypertrophic cirrhosis is believed to be distinct from the "hypertrophic" fatty cirrhosis which represents an intermediate stage between the fatty liver and the atrophic cirrhosis of chronic alcoholic addicts or other conditions in which dietary deficiency is probably the most important etiologic factor.

Beriberi in Japanese Prison Camp.—Hibbs reports observations on beriberi over a period of thirty-four months on about 8,000 Americans who had surrendered on Bataan and Corregidor. Beriberi had the highest incidence of vitamin deficiency disease, every one in the camp having some form of beriberi at one time or another. It also was responsible for more deaths than any other vitamin deficiency disease. A group of 96 cases of beriberi were selected for a therapeutic response experiment by a Japanese doctor. American doctors conducted the study. The patients selected had the severest form of painful feet. They all demonstrated the typical "Cabanatuan shuffle" and sensory manifestations of symmetrical ascending peripheral neuritis of beriberi. Conclusive results were not obtained because the patients were still issued a borderline starvation diet. The dosages and length of treatment were inadequate. Thiamine hydrochloride first corrected the anorexia, nervous manifestations, tachycardia and arrhythmia and improved the exercise tolerance of the heart in cases of beriberi. Beriberi peripheral neuritis responded sooner to the entire B complex than to thiamine hydrochloride alone. The intrathecal route of administration was no more efficacious than subcutaneous injection. Complete saturation of the body with thiamine hydrochloride was not attained by a short course of large doses. The author stresses that more vitamins can be bought in a grocery store than in a drug store. There may be nutritional causes of polyneuritis other than lack of thiamine. Palmar and plantar erythema are consistently seen in dry beriberi. "Beriberi spots" is a newly described skin lesion probably due to thiamine deficiency. Motor manifestations are often minimal or lacking in beriberi peripheral neuritis. Posterolateral column degeneration of the spinal cord in malnutrition is probably due to lack of vitamin B_1. An irreversible optic atrophy may result from severe beriberi.

Injection of Tissue Extract in Treatment of Basal Epithelioma.—At the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital patients were selected with small basal cell epitheliomas varying in size from that of a pea to 3 or 4 cm. in the longest dimension. All types of basal cell epitheliomas were taken indiscriminately. Before treatment was given, a colored photograph was taken of the lesion and a biopsy was performed. The patient was then given a series of weekly injections of either spleen or liver extract. The extracts were produced from normal human spleens and livers obtained at necropsy from persons who died suddenly as the result of accident or heart failure. Amersbach and his co-workers review observations on 21 patients with basal cell epithelioma who were treated by this method. The lesion of 1 treated with spleen extract failed to regress. Fourteen have had complete regression and disappearance of the lesion. The remaining 6 are still under treatment, but all have shown regression. In none of the cases observed since completion of the treatment have there been signs of recurrence in the period of one to two years.

Alloxantin in Experimental Production of Diabetes.—Herbut and his colleagues found that alloxantin administered by the intravenous route produced an effect similar to that of alloxan. There was temporary hyperglcemia followed by temporary hypoglycemia and then either transient hyperglycemia or, in a few of the animals, permanent hyperglycemia with excretion of sugar in the urine. Undesirable side effects consisted of thrombosis of the veins of the ears, severe pulmonary congestion and edema, and necrosis of the central portions of the hepatic lobules. The authors conclude that although the diabetogenic action of alloxantin is unequivocal, it is not a good substitute for alloxan because it is difficult to administer, it is toxic, and nonlethal doses will produce diabetes in only a few animals.

Surgical Approach to Hypertension.—De Takats and his associates discuss observations on 52 patients, stressing the importance of rigid selection. In the first group, in which there was a clearcut indication for operation, the ages of the patients did not exceed 40 years. The systolic pressure varied between 200 and 150 mm. of mercury and the diastolic from 120 to 100. In these patients the pressure comes down to normal during sleep. The authors include in this group early adolescent hypertensive patients who are completely asymptomatic but have a bad family history and show exaggerated vasomotor reactivity. Also included are some patients who have advanced vascular damage in the retina, heart or kidney but who relax under sodium amytal to a diastolic pressure of 100 mm. In the 17 patients of this first group, the response was gratifying. Only 2 had recurrent hypertension, which was corrected after completion of a technically incomplete operation. In the second group operated on by the authors operability was debatable, but it is pointed out that some of these patients obtained unexpected relief and others had a slightly lower pressure but the organic damage was permanent and progressive. The patients in this group had organic vascular damage. Six of the 28 patients of this group showed recurrence. The third group consists of patients in whom splanchnic section is not indicated. Such patients have large recurrent hemorrhages or exudates in the retina. The diastolic pressure is extremely high and fixed. The urine contains albumin, casts and red cells. The urea clearance is less than 50 per cent of normal. Five such patients were operated on and no effect was noted. The authors discuss some of the problems of anesthesia, especially the avoidance of accumulation of carbon dioxide. They are convinced that so far a method has not been found which gives patients with hypertension as much benefit as the transdiaphragmatic splanchnic nerve section combined with dorsolumbar sympathetic ganglionectomy.

Intraperitoneal Administration of Sulfonamides in Peritonitis.—Young and Cole found that succinylsulfathiazole and phthalylsulfathiazole implanted in the peritoneal cavities of human beings or dogs are rapidly absorbed into the blood stream. The average peak level of the two drugs at four hours was 4 and 5 mg. per hundred cubic centimeters respectively. The rate of disappearance from the peritoneal cavity is much more rapid than that of sulfathiazole or sulfadiazine and resembles more closely the rate of disappearance of sulfanilamide. The temporary adhesions observed after the intraperitoneal implantation of sulfadiazine and sulfathiazole are not observed after the use of either drug. The drugs can be given intraperitoneally to dogs in a dose of at least 1 Gm. per kilogram of body weight without reaction. The authors have adopted a dose of 0.1 Gm. per kilogram of body weight for human beings, but in view of the low toxicity in animals it appears that the dose could be increased. The series treated by the authors is too small to allow comparison with a control series. Since both drugs are extremely effective in reducing the Escherichia coli count of the stool when given orally, it is reasonable to suppose that they could also be effective against the same organism occurring as a contaminant following intestinal resection. Since the blood level is slightly higher and more prolonged with phthalylsulfathiazole, this drug might be expected to be more effective than succinylsulfathiazole.

Selling Medical Plans to Doctors. T. L. Williams.—p. 240.

Sudden Death in Obstetrics.—Sudden death in the obstetric patient is usually due to shock, hemorrhage or a combination of these two factors. Shock in the obstetric patient seems to be caused by (1) preeclampsia and eclampsia toxemia with or without the precipitating factors of anesthesia, surgery, trauma and blood loss, (2) dystoxia followed by exhaustion, dehydration, difficult forceps delivery and blood loss and (3) anaphylactoid reactions following blood transfusions and drugs. Johnson has seen fatal anaphylactoid reactions from intravenous injection of sulfanilamide, blood transfusion and in 2 cases in which ergotrate had been given. He has seen profound shock follow the administration of 1 minim of pitocin. Intradermal tests for sensitivity require only a few minutes and would avoid such grave complications. Recently 100 intradermal tests with ergotrate have been made while the patients were on the delivery table. There were 98 negative, but 2 positive reactions. Fatal hemorrhage may be brought on by postpartum hemorrhage from such causes as uterine atony, extensive cervical lacerations and ectopic pregnancy. The author adds to this group spontaneous separation or manual removal of the placenta in abdominal pregnancies and manipulated placenta previas. Shock from hemorrhage may cause death, but it is relatively infrequent when uncombined with the other causes of obstetric shock.

Effect of Tobacco Smoke on Kahn and Hinton Reactions.—Breazeale and Dunn carried out experiments to test the effect of tobacco smoke on the Kahn and Hinton reactions. Serums were drawn for routine examination by the methods of Kahn and Hinton. Control tests were made in a room free from chemical fumes. The serum remaining after running the control test were then divided into two portions. The first portion was subjected to cigar smoke for a period of thirty minutes and then the standard Kahn and Hinton tests were run in an atmosphere of cigar smoke. The second portion was run only in the atmosphere of smoke without previous exposure. It was found that exposure to tobacco smoke increases the "titer" on serum from 1 to 3 points. On visual reading the serums exposed to smoke were more strongly positive than were the controlled serums. Serums that were exposed to smoke before and during the examination gave a more strongly positive reaction than did serums exposed to smoke only during the actual performance for the test itself. The authors conclude that tobacco smoke in sufficient concentrations will influence the accuracy of the various serologic tests for syphilis.

Carrier of Hemolytic Streptococci.—The number of beta hemolytic streptococci captured by sterile handkerchiefs after blowing the nose, sneezing and coughing was compared by Hamburger and Green in carriers exhibiting positive nose and throat cultures and those with positive throat but negative nose cultures. Sneezing, coughing and forcible breathing on blood agar plates were also investigated. Millions of hemolytic streptococci were frequently expelled during a single noseblow by carriers with positive nose cultures. Extensive contamination of the hands by these bacteria was found in carriers exhibiting positive nose cultures but very little of the hands of carriers with positive throat but negative nose cultures. Gross contamination of the hands may occur instantaneously during a single noseblow. Relatively few hemolytic streptococci were expelled by coughing. Variable numbers were expelled by induced sneezing. Nine out of 10 throat carriers with negative nose cultures expelled very few streptococci by sneezing. Carriers with positive nose cultures, however, were sometimes capable of sneezing out great numbers, though the experiments suggest that most of the streptococci were contained in nasal secretion which would not be finely atomized or propelled very far from the sneezer. It is concluded that blowing the nose is the most important of the respiratory activities which result in the dissemination of hemolytic streptococci under epidemic conditions.

Gastroenteritis from Salmonella Pullorum.—According to Mitchell and his associates Salmonella pullorum is a common cause of disease in chickens and is known to be present in the eggs of infected fowls and accordingly may be found in food products. This micro-organism is thought not to be concerned with human disease and is usually described as nonpathogenic for man. Recently the Army Air Forces Central Diarrheal Disease Control Laboratory of the Army Air Forces School of Aviation Medicine investigated an extensive outbreak of gastroenteritis among personnel at an army air base. The evidence obtained indicated that this outbreak could be attributed to the ingestion of food prepared from uncooked eggs and that Salmonella pullorum was prominently associated with the epidemic. The outbreak of gastroenteritis involved a total of 423 persons who required medical treatment. Of this number 172 required hospitalization. The source of the infection could be traced to rice pudding containing eggs served at three successive meals. This rice pudding formed the sole common link between all the patients. Salmonella pullorum was isolated from 11.7 per cent of the hospitalized patients, and this organism was believed to have been the probable cause of the infections and to have been introduced into the rice pudding by infected eggs. This outbreak is the first reported large scale epidemic of human gastroenteritis associated with S. pullorum. Uncooked eggs and egg products infected with S. pullorum constitute a potential source of outbreaks of human gastroenteritis.

Juvenile Rheumatoid Arthritis.—Since the organization of an arthritis clinic at Columbia Presbyterian Medical Center in 1928, Coss and Boots have observed 56 cases of rheumatoid arthritis in children. This group includes cases in which the onset was at 12 years of age or earlier and represents 4.9 per cent of all cases of rheumatoid arthritis. The authors have not used the term Still's disease, since Still's disease suggests a distinction between conditions the differences in which are not related to the nature of the disease process but to the reaction of the body against that process as it varies in different age groups. The presence of splenomegaly, hepatomegaly or generalized glandular enlargement is not a necessary part of the diagnosis of juvenile rheumatoid arthritis, although it is more frequent than in adult arthritis. Cardiac changes were seen in some of the patients and, if the arthritis had disappeared early with no residuum, one would be inclined to classify them as rheumatic fever. The authors found that gold therapy is no more dangerous in children than in adults. Roentgenographic comparisons of the various forms of arthritis indicate four criteria as most characteristic of juvenile rheumatoid arthritis: decalcification, bone destruction, joint space narrowing and soft tissue changes. Roentgenologic studies were available in 47 of the 56 patients with at least one of the criteria present in all. Unusual skeletal changes resulting directly from early rheumatoid arthritis usually occur when the disease begins before the second dentition and in the first three years of life.

Action of Quinacrine on Ventricular Fibrillation.—Melville observed that intravenous injections of quinacrine hydrochloride can prevent the development of ventricular fibrillation following injection of epinephrine during chloroform administration in dogs anesthetized with pentobarbital. This protective action of quinacrine is also demonstrable after atropinization or vagotomy. Electrocardiograms taken during the rise in blood pressure following injection of epinephrine in the pentobarbitalized dog show characteristic early diphasic alterations in both P and T waves. These alterations are accentuated if chloroform is being administered but under similar conditions are antagonized by quinacrine. It is suggested that this protective action of quinacrine is primarily a coronary phenomenon. Thus quinacrine (a coronary dilator agent) might offset either an initial reduction in coronary blood flow or some impairment in myocardial nutrition induced by epinephrine under the conditions described.

Pneumothorax for Early Bronchiectasis.—Hennell suggests as objectives in the treatment of bronchiectasis (1) diminution of the trauma of respiration by decreasing its force or by eliminating it entirely in the diseased portion of the lung; (2) decrease in or elimination of the trauma of cough; (3) counteraction of the increased pull on the diseased bronchi because of a lowered intrapleural pressure incidental to atelectasis or fibrosis of the pulmonary parenchyma; (4) elimination of the infection in the lung and bronchi. All patients were successfully treated by the induction of a low tension pneumothorax. There was a selective collapse of the involved portion of the lung, the highly negative intrapleural pressure was brought to an approximately normal level; the cough promptly decreased and then disappeared within one to four weeks; infection subsided promptly and permanently. Pneumothorax therapy should receive first consideration in cases of early bronchiectasis. If judiciously employed, pneumothorax has no mortality, no morbidity and no serious complications. The use of pneumothorax does not preclude the subsequent employment of radical surgical therapy if the pneumothorax is relinquished when success is not achieved in a reasonably short time.

Dextrocardia and Bronchiectasis.—Russakoff and Katz report 2 instances of dextrocardia and bronchiectasis and present evidence that transposition of the viscera is attended by a high incidence of other abnormalities. In reviewing the files of the Mayo Clinic from 1920 through 1941 Olsen found 85 cases of dextrocardia. Of these, 14 were discovered to have an associated bronchiectasis, an incidence of 16 per cent. During this identical period a diagnosis of bronchiectasis was made on less than 0.5 per cent of all other patients investigated. The authors consider that the coincidence of bronchiectasis with visceral transposition is unusually high. They think that this puts physicians under obligation to adopt a somewhat different attitude toward cases of dextrocardia. It is no longer sufficient to inform the patient of transposition of the abdominal viscera in cases of situs inversus to avert the catastrophes of improperly interpreted contralateral abdominal manifestations Besides a search for other anomalies, a thorough investigation of the upper respiratory system and the bronchopulmonary tree should be an integral part of a complete clinical study.

*Rabies in Washington State H H Kretzler.—p 666

Salmonella Fever.—Bender reports 5 cases belonging to that group of salmonella infections usually classified as enteric fever or salmonella fever seen in an overseas hospital on Luzon, P I. The epidemiologic aspects appear to be about the same as those observed in typhoid Salmonella paratyphi A, the etiologic agent in the first 3 cases, is closely related to Salmonella typhi (Eberthella typhosa) both in pathogenicity and in natural distribution. The clinical picture is so similar to typhoid that only a bacteriologic diagnosis can differentiate the two In the fourth case Salmonella enteritidis was demonstrated and in the fifth case blood cultures were positive for group C Salmonella, type undetermined. Positive blood cultures were obtained in all 5 cases. The vagaries of the infection are illustrated, oscillating from a severe systemic infection with pulmonary involvement, cholecystitis and subsequent perforation of the gallbladder to a moderate febrile course with only malaise and headaches. The diagnosis of sporadic cases of salmonella fever necessitates constant awareness of the process with subsequent demonstration of the organisms in the blood, feces or urine While recognition of the basic etiology will affect the treatment but little, it may prevent unnecessary surgical intervention and is important from the standpoint of isolation precautions

Rabies in Washington State.—Kretzler reports 8 cases of human rabies that have occurred in the state of Washington. The Pasteur treatment is not wholly devoid of danger. With present laboratory methods the danger of contracting rabies from the vaccine is remote but is always present. Figures regarding the incidence of this complication vary greatly. Of the 8 cases reported here paralysis developed in 3. Recovery occurred in 2 of these without residual paralysis, but the third patient still had much spasticity of the lower extremities two years after onset and still needed crutches or braces to enable him to walk. Age seems to be one of the factors that influences the likelihood of paralysis, as it is rarely seen in children. The more intense the treatment, the more likely is the development of paralysis. Vaccination with the dried cord, the original Pasteur method, results in the greatest incidence of paralysis. The cerebral substance of the rabid animal rather than the cord substance was held by some to be responsible for the complication.

Modified Field Stain for Rapid Staining of Thick and Thin Blood Smears T. P. Pesigan and E. Y. Garcia —p 165.

Cancrum Oris—Tupas and Jongco say that cancrum oris, also known as noma or gangrenous stomatitis, showed a rise in frequency during the later years of the Japanese occupation and decreased again in 1946. They think that this can be attributed to the scarcity of food and to poor hygienic and living conditions prevailing during the period of occupation. They review observations on 15 cases of cancrum oris seen in the course of one year. Only 2 of the patients died. This mortality rate of less than 14 per cent is a great improvement over mortality rates of from 70 to 100 per cent given in the earlier reports The author ascribes these favorable results to the combined use of sulfonamides and penicillin. The mouth was first cleansed with an antiseptic solution, usually dilute potassium permanganate; sulfathiazole or sulfadiazine powder was applied locally to the lesions. In addition, 8 patients received either sulfathiazole or sulfadiazine by mouth. Seven patients were given sulfathiazole or sulfadiazine by mouth and penicillin intramuscularly. The dose of penicillin varied from 100,000 to 250,000 units daily. All of the 7 patients who received sulfonamides and penicillin recovered.

*Fluorescein—Aid in Gastroscopy. H. M. Robinson.—p. 303.

Fluorescein in Gastroscopy.—Robinson used fluorescein in outlining ulcers of the gastric mucosa which otherwise might be overlooked or might appear indefinite on gastroscopy. The Schindler procedure was unaltered except that 10 cc. of the fluorescein was permitted to enter the stomach through the Ewald tube after the gastric contents had been drained The gastroscope was then inserted and the stomach inspected in the usual manner The author presents the history of 4 cases which are representative of 22 in which this method was used Fluorescein aids in outlining and demonstrating the ulcer and thus makes possible a more accurate estimate of the diameter of the ulceration.

Anemias Associated with Nutritional Disorders.—All morphologic types of anemia are found in patients with nutritive failure Some of these result from an inadequate intake in specific nutrients A deficiency in extrinsic factor results in macrocytic anemia, of iron in microcytic anemia, and occasionally of ascorbic acid or other factors in normocytic anemia Among patients with microcytic anemia Vilter and Spies detected a considerable number, all female, who seemed to have the Plummer-Vinson syndrome, or sideropenic dysphagia These patients, in addition to evident pallor, complained of burning of the tongue and difficulty in swallowing. Some had been grinding their food for years The tongue usually showed atrophy of the papillae and appeared smooth, pale and glistening. Sometimes there was an associated cheilosis or angular stomatitis Anorexia, flatulence and constipation were usual Spoon nails were occasionally observed and also a spotty but coalescent brown pigmentation over the face. Fluoroscopic studies of the upper part of the esophagus frequently revealed a semilunar membrane partially obstructing the lumen and an adjacent narrowing of the esophagus. Hypochlorhydria was usual in patients with anemia and dysphagia. There are two theories about this syndrome On the one hand the dysphagia can so alter the dietary that there is iron deficiency and anemia develops; on the other, it is possible that the alterations in the esophagus are secondary to the anemia or the iron deficiency. Iron alone is effective in this microcytic, hypochromic anemia Liver factor deficiency (macrocytic anemia) may be treated with liver extract or synthetic folic acid, iron deficiency with ferrous compounds and the anemia of scurvy with ascorbic acid Therapeutic combinations of these specific substances for the treatment of anemias are economically wasteful and have been used only as the result of misconceived advertising and indifference in diagnosis.

Leukanemia.—Foy and his associates report the occurrence in a woman aged 24 of a condition which corresponds to Leube's original description of the syndrome of leukanemia and which raises questions relating to the maturation of the erythroid and myeloid cells Hematologic, clinical and postmortem aspects are described in detail The disorder commenced as a typical macrocytic anemia, with Ehrlich's megaloblasts and giant stab cells in the sternal marrow Free acid was present in the gastric juice after histamine In the later stages of the disease the blood became leukemic, with 30,000 to 189,000 white cells, 80 to 90 per cent of which were myeloblasts, some paramyeloblasts were present which are regarded as pathognomonic of the myeloblastic leukemias It is suggested that the red and white cell changes which occur in leukanemia are due to a maturation defect in the stem cell (hemocytoblast) which affects both the erythroid and the myeloid series, and that the defect may be due to the absence of some unknown factors necessary for the proper maturation of the hemocytoblast and the orderly formation and development of both red and white cells

Thrombosis and Atherosclerosis.—Duguid states that in his pathology classes sections of a thrombosed coronary artery were used to illustrate the process of canalization The artery, which had an organized thrombus with many channels running through it, provided a large number of sections, until a point was reached at which the formation changed Instead of many channels there was now a single lumen surrounded by a greatly thickened wall in which were foci of fatty degeneration The picture had changed from thrombosis to atherosclerosis. In order to see how this had come about, the sections were examined in serial order, whereupon it was found that the thrombosis was not limited to the region in which there was canalization but extended farther along the vessel in the form of a thick inner lining which, being organized and adherent, had the appearance of an intimal overgrowth Frozen sections from 26 cases of this condition showing organization of coronary thrombosis suggest that many of the lesions classified as atherosclerosis are arterial thrombi which, by the ordinary process of organization, have been transformed into fibrous thickenings. Red thrombi are prone to softening with fatty degeneration, and many of the "atheromatous" patches found in arterial thickenings appear to be the result of this process

Hepatodiaphragmatic Interposition of Colon.—Out of 20,000 roentgenoscopies in school children, army inductees and factory workers, Hubacher observed 17 patients (0 85 per thousand) with hepatodiaphragmatic interposition of the colon This condition was also observed in 5 of 5,000 cases (1 per thousand) in which chest roentgenograms were made Ten cases of hepatodiaphragmatic interposition of the colon were observed among 1,000 roentgenoscopies which were performed in infirmaries for the insane Reports of 22 additional cases in persons between the ages of 11 and 86 years are presented Hepatodiaphragmatic interposition of the colon occurs more frequently than would appear from the European literature Men are more frequently affected than women. In 21 of the 22 cases the condition was congenital and in only 1 case was it acquired In only a few cases the condition may be a sequel to a pathologic condition in the abdomen or thorax, but causal relationship between hepatodiaphragmatic interposition of the colon and other clinical symptoms, such as subileus, chronic constipation, upward displacement of diaphragm and transverse position of the heart is possible Diseases of the myocardium, of the coronary arteries and of the aorta, often associated with hepatodiaphragmatic interposition, may have some relationship to this condition Contrary to the statements in the literaure, posterior interposition of the colon was observed three times as often as the anterior interposition Chest roentgenoscopy is the diagnostic method of choice in cases of persistently displaced hepatic flexure and in cases with constant gas distention in the large intestine

*Prevention of Shock by Vitamin C. Christiane C. D. Pasqualini —p 554.

Prevention of Shock by Vitamin C.—Pasqualini bled guinea pigs to the appearance of collapse. The blood was collected in a syringe containing heparin solution. As soon as collapse appeared, 25 per cent of the volume of blood was reinjected. Blood pressure rose for fifteen minutes and again fell. The remaining 75 per cent of heparinized blood was immediately reinjected. Blood pressure rapidly rose, but shortly after it fell and the animals died in about four hours The experiment was repeated in groups 2 and 3 of animals which were given prior to being bled an intraperitoneal injection of 200 mg of vitamin C (group 2) or an equivalent volume of isotonic solution of sodium chloride One out of 18 animals in the vitamin C experiment and 15 out of 17 controls died from hemorrhagic shock The animal which had vitamin C and died survived for twenty hours The controls died within a few hours The 17 survivors in the vitamin C group returned to normal health for an indefinite period

Kyphosis in Tetanus W. T Snoek and N Schulte —p 580.

Influence of War Conditions on Incidence of Tuberculosis.—Ruys says that before the war infection with the bovine type of tuberculosis was comparatively frequent even in the cities of the Netherlands. Investigations covering the period between 1933 and 1938 revealed that in cities with over 100,000 inhabitants bovine tuberculosis accounted for 9 per cent and other forms of tuberculosis for 21 per cent of the pulmonary disorders among children under 15 years of age. For adults the corresponding figures were 1 per cent and 20 per cent respectively. After 1940 the conditions changed. As nutrition became steadily poorer, tuberculosis increased in severity and extent. Isolation in sanatoriums became impossible in many cases of open tuberculosis, and chances of aerogenic infection with the human type of tubercle bacilli increased greatly. Since 1940 the milk in the large cities has been pasteurized chiefly to standardize the fat content, which has become steadily less, adults receiving only skim milk and finally no milk at all A table comparing the incidence of new cases of tuberculosis before and during the war in Amsterdam reveals a great increase among adults during the period of poor nutrition. However, a table listing the incidence of bovine and human infections in children before and during the war shows that whereas before the war the incidence of bovine tuberculosis was 9.6 per cent, during the war years it was only 1 8 per cent.

Clinical Aspects of "Pancreatic Cirrhosis" in Infants. Ada Middelhoven —p. 693.
Brachyesophageal Diaphragmatic Hiatus Hernia. R. P. van de Kasteele. —p. 696.
*Familial Cirrhosis of Liver and Osteoporosis A. G. Schoo.—p 700
Gargoylism H. M. Brouwer Frommann —p 705.

Familial Cirrhosis of Liver and Osteoporosis.—Schoo observed a girl aged 6 years who had an enlarged liver and in whom biopsy indicated cirrhosis. She also had glycosuria, polydipsia and a skeletal disorder resembling rickets. For the last six months she exhibited pain to touch, and walking was impossible. Two sisters of this girl had died of a similar disorder, whereas a brother was healthy Gerstenberger in 1933 described the concurrence of hepatic cirrhosis and rickets in 3 children In the case of "rickets" that accompanies hepatic cirrhosis, vitamin D must be administered in large doses In the reported case some improvement was observed when an intramuscular injection of 600,000 international units was given Improvement progressed after a second and third injection of this dose. Pain in the legs persisted; the girl could sit but not stand; the weight decreased further, and it is likely that the general condition will deteriorate as the result of the hepatic cirrhosis

Book Notices

Job Placement of the Physically Handicapped. By Clark D. Bridges, Director of Conservation Services, Zurich Insurance Companies, Chicago. Cloth. Price, $3.50. Pp. 329, with illustrations. New York & London: McGraw-Hill Book Company, Inc., 1946.

This book appears to be a compilation of material from many sources (there are two pages of acknowledgments plus "many others who contributed"). Presentation of the material is brief, graphic and simple. The graphic display of job analysis and hazard is excellent. The simpleness of the anatomic and medical discussions is astounding; in fact it rivals the old time "doctor books" that were common during the last century. Surely employers who are intelligent enough to operate a large business successfully today can understand a more exact description of medical subjects. The oversimplification in this field is apt to mislead the uninformed reader; also the collection and presentation of this material are arranged for a person who has little or no background to understand the subject most similar to a primer designed for beginners. The placement considerations following the discussions of various diagnoses and material reprinted in appendixes will be of interest to physicians who are treating workers, but surely industrial physicians are already familiar with this material.

Prescribing Occupational Therapy. By William Rush Dunton, Jr., M.D. Second edition. Fabrikoid. Price, $2.50. Pp. 151. Springfield, Illinois: Charles C Thomas, 1945.

This edition continues to emphasize the value to patients of the effect of sedative work, assignments which need concentration and other general considerations. In fact the emphasis placed on these objectives leaves the reader uninformed about the strides that have been made since the first edition. In the chapter on the significance of occupational therapy a modern book should mention the use of this technic as an aid to diagnosis. Lately several reports have indicated that the occupational therapist can be used in diagnostic psychiatry as an aid in discovering the underlying cause for a particular individual's psychosis. Orthopedic surgery can use this "therapist" as an aid in diagnosing the present capacity of muscles and joints as well as prognostication based on response of injured parts to graded work load. Other examples of the diagnostic aids furnished by correct use of occupational therapy could be described, and these should be in the chapter on significance.

Specific improvements have also been made in the field of therapy of mental, orthopedic and convalescing patients, yet these are not mentioned in this portion of the book. In fact the broad principles formerly ascribed to occupational therapy could be undertaken by a poorly trained person. It is necessary to emphasize these newer developments to indicate that the modern occupational therapist needs adequate training before she is entrusted with these responsibilities.

If this edition is designed for physicians there is entirely too much elementary description and classification of mental and physical diseases. There is also a tendency to emphasize the mental conflicts associated with physical disease without equal stress being placed on specific prescriptions designed to cope with the physical handicap. If this book should be supplemented with newer knowledge of occupational therapy it might still be useful for beginning students.

Lectures on Preventive Medicine. By Harvey Sutton, O.B.E., M.D., D.P.H., Professor of Preventive Medicine, Director of School of Public Health and Tropical Medicine, University of Sydney, Sydney. Cloth. Price, 27 s. 6d. Pp. 658, with illustrations. Sydney: Consolidated Press, Ltd., 1944.

Easy informality combined with a scholarly presentation make these collected lectures interesting reading. The subject is considered under four main headings, the first of which is human life history. In this, eight chief subjects, including heredity and genetics, maternal and infant mortality, child welfare, industrial hygiene and personal and mental hygiene, are presented with numerous subheadings. In the next section environmental influences are discussed. Ventilation, heating, water, waste disposal and housing are considered, but the most interesting presentation is that under the heading of vitamins. This is a comprehensive discussion, giving in great detail all established facts regarding these elements. Proper balance is maintained by consideration of foods as the basic source of vitamins and emphasis on the importance of an adequate, well rounded diet. A lecture on alcohol states that "alcohol is a third-rate food, a second-rate drug and a first-rate poison," and this analysis is then discussed in detail. The third section, on communicable diseases, contains lectures dealing with avenues of infection, carriers, animal diseases, vectors, disinfection and infectious diseases. Following the fourth section, a brief consideration of public health administration, there is an appendix containing details on construction of a pedigree chart, vaccination against smallpox, tabular data of stages of growth including the now less widely used height-weight charts, and excellent material on milk and meat inspection. These lectures, though slanted somewhat for the Australian point of view, are of considerable general interest.

Growth and Development of the Young Child. By Winifred Rand, A.B., R.N., Mary E. Sweeny, A.M., M.S., and E. Lee Vincent, Ph.D. Fourth edition. Cloth. Price, $3. Pp. 481, with 63 illustrations. Philadelphia & London: W. B. Saunders Company, 1946.

With the publication of this edition the authors have brought their textbook well up to date and have done extremely well in orienting their book to modern ideas about child growth and development. While it emphasizes mental and emotional development rather than the purely physical, the book does contain excellent chapters on physical growth. Emphasis is placed on the preschool years rather than on infancy, although data on this period are included. In appraising the book, one is impressed with the fact that, while it is not the ultimate answer to our crying need for a standard textbook on human growth and development, it is as good an attempt at fulfilling such a need as has yet been published. No one or two or three people could possibily write a complete treatise on this all inclusive subject. The final answer must be a compilation of the work of many capable investigators, knit together by some experienced editor. The publisher has done a good job of printing. Illustrations are ample and there is a good index. A medical man reading this book will find many places where the information is perhaps not as complete as he would desire, but the information given is accurate. The average doctor will find also a wealth of material about which he is uninformed and which will be extremely practical to use in his daily contacts with parents and children. The bibliography is excellent and will assist him if he cares to delve deeper into subjects which are too superficially handled. The book should be useful in planning courses in growth and development for students and as a reference; but its greatest value will lie in its valiant attempt to relate the many facts of growth to the problems of actual living with children.

Music in Hospitals. By Willem van de Wall, Head, Adult Education Section, Education Branch, Internal Affairs and Communications Division Office of Military Government for Germany, U. S. Paper. Price, $1. Pp. 86, with 1 illustration. New York: Russell Sage Foundation, 1946.

Music in Medicine. By Sidney Licht, M.D. Cloth. Price, $3. Pp. 132. Boston, Massachusetts: New England Conservatory of Music, 1946.

Both these books on "music therapy" are apparently attempts to justify the use of music in the program of care of patients and to familiarize musicians with the organization developed for this purpose. One author has had considerable experience as an educator in the study of the psychology of music. The other is a physician who overlooked the only scientific article published on this subject by the American Medical Association.

Both booklets emphasize the necessity of having music prescribed by physicians who are responsible for the patient's care. Both fail to mention that it is only in the group of patients who remain in hospitals for long periods that there is even a chance for the functional use of music. General hospitals admit about 90 per cent of all patients, and the average stay for these patients in nonfederal general hospitals is only twelve days. Mental, tuberculous, cardiac and reconstructive orthopedic patients are hospitalized for longer periods, but general statements regarding music for these types of patients cannot give musicians or the public a clear understanding of the limitations of music for all types of patients. Little or no functional value of music can be expected for patients whose period of hospital stay is short, and therefore the only other value is diversional or for entertainment. It is unlikely that general hospitals will be interested in supplying personnel for the entertainment of their patients.

The functional approach of music should be under the direction of a qualified and experienced occupational therapist rather than musicians. It is only the adequately trained and experienced therapist who will have the proper knowledge of anatomy, physiology, psychiatry and psychology used in making music a functional type of treatment. Such a philosophy is implied by both authors but is not stated. Then, as music becomes a responsibility of the occupational therapist, she may request musicians to aid but never to assume control. Furthermore, music has for years been considered as an occupational therapy modality in both functional and diversional recreation. The functional use of music as an art or craft in occupational therapy has already received recognition by the American Medical Association in Music as a Modality of Occupational Therapy, by Arthur Fultz (*War Med.* **5**:193 [March] 1944).

Compulsion: The Key to Collectivism: A Treatise on and Evidence of Attempts to Foist on the American People Compulsory Health Insurance, and Explanation of the Implications Involved. Paper. Pp. 192, with illustrations. The National Physicians Committee for the Extension of Medical Service, Inc., 75 E. Wacker Drive, Chicago 1, 1946.

This study presents a readable and instructive account of the forces behind the agitation for a system of federally controlled compulsory sickness insurance in the United States and the technics employed by the agitators to gain their objective. Scattered throughout the pages of this brochure are pertinent excerpts from the testimony presented before the Senate Committee on Education and Labor in connection with the extended hearings on the Wagner-Murray-Dingell bill. Section B of the study is devoted exclusively to such testimony and to the ten point program of the American Medical Association. The chapter headings of section A are indicative of their contents: The Wagner-Murray-Dingell Bills and their Historical Background, the Bureaucratic Propaganda Front, Government Propaganda for Political Medicine, The Misused Draft Rejection Statistics, Organized Medicine's Efforts for Better Medical Care, The Why of Physician Opposition, Probing for Facts, An Elder Statesman Testifies, and Compulsion the Key to Collectivism. Every physician should possess and absorb the contents of this study.

Physicans' and Dentists' Assistants: The Outlook for Women in Occupations in the Medical and Other Health Services. United States Department of Labor, Women's Bureau, Bulletin 203, Number 11. Paper. Price, 10 cents. Pp. 15, with 4 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1946.

Another excellent presentation of material for vocational guidance of women can be found in this pamphlet. This is the eleventh pamphlet in the series entitled "The Outlook for Women in Occupations in the Medical and Other Health Services." The entire series should be made part of the armamentarium of every vocational counselor. Mrs. Marguerite Zapoleon has followed an outline for this booklet similar to the arrangement of the preceding publications. Pertinent information is given, changes that have occurred as a result of the war are emphasized and an attempt is made to forecast some of the future developments. A practical approach is used by describing the earning power, hours of employment and the amount of advancement that can be expected. Appendix A, in each issue of the series, summarizes the important facts in tabular form.

Penicillin: Its Practical Application. Under the General Editorship of Professor Sir Alexander Fleming, M.B., B.S, F.R.C.P., Professor of Bacteriology in the University of London, St. Mary's Hospital, London. Cloth. Price, $7. Pp. 380, with 59 illustrations. Philadelphia: Blakiston Company, 1946.

This book, prepared under the editorship of Sir Alexander Fleming, is a comprehensive and authoritative compendium of our present knowledge of penicillin in all its aspects. Although the twenty-eight contributors are British, the American contributions to penicillin therapy are not slighted. The value of the book is enhanced because of its complete presentation of all the British work on this drug, much of which is not familiar to American physicians.

The first part of the book deals with the history, chemistry, manufacture, pharmacy, pharmacology and bacteriology of penicillin. These chapters are well written and of interest even to the general practitioner. The chapters on chemistry and pharmacology are particularly good, although the book was prepared before the recent information on the pharmacologic differences between the various penicillin fractions was available. The twenty-one chapters on the clinical use of penicillin are exceedingly well done and present a conservative point of view on the application of penicillin to a wide variety of bacterial infections commonly encountered in medical practice. The use of penicillin in the various medical and surgical specialties is presented authoritatively, and adjuvant medical and surgical treatment is stressed.

Only minor criticisms may be offered of this textbook. Mention is not made of the various chemical methods of penicillin assay which have been under study for the past two years. Although a comprehensive discussion of penicillinase is included, mention is not made of the use of this enzyme to distinguish between penicillin and nonspecific inhibitory substances in serum when one is performing assays on blood specimens. Considerable emphasis is given to pharmaceutic preparations of penicillin, particularly those for local application; this emphasis may lead the less informed physician to use local treatment where better results might be obtained from systemic therapy. The book is well illustrated in the first part, but greater use of illustrations could have been made in the section dealing with the clinical use of the drug. At the end of each chapter an excellent list of references is given, and the index at the end of the book is useful. In common with other British textbooks, the style of writing appears superior to the usual American book. This volume can be recommended to students, general practitioners and specialists without reservation.

The Vitamins in Medicine. By Franklin Bicknell, D.M., M.R.C.P., and Frederick Prescott, M.Sc., Ph.D. A.R.I.C., Clinical Research Director, the Wellcome Foundation, London. Second edition. Fabrikoid. Price, $12. Pp. 916, with 208 illustrations. New York: Grune and Stratton, 1946.

This book is a review and appraisal of our current knowledge of the vitamins, with correlation of their chemistry, physiology, nutritional importance and clinical uses. It may be considered as a source book in that it contains approximately 4,500 references to the literature, and the discussion is extensive and often detailed. Information of this type and scope presumably has not been collected previously in a single work. While the authors have attempted a critical evaluation of the literature, they themselves state that they cannot hope to have avoided errors of judgment in selection and interpretation of the literature. Though critical readers may expect to find a number of interpretations at variance with their own, the book nevertheless is worth while and should serve its purpose well. It should be valuable to any one with a scientific interest in the vitamins. It is profusely illustrated, and the illustrations are clear and well chosen. Comment on specific phases is not attempted because of the great variety and extensive ramifications of the subject matter.

The Chemical Composition of Foods. By R. A. McCance and E. M. Widdowson. Medical Research Council, Special Report Series No. 235. Second edition. Fabrikoid. Price, 6s. Pp. 156. London: His Majesty's Stationery Office, 1946.

New analytic data are in constant demand in the rapidly growing science of foods and nutrition. In order to provide investigators, particularly in Great Britain, with such material, analytic work has been sponsored by the council since 1925. In this book some new unpublished data have been added. Old data have been reappraised and revised or deleted as indicated by newer evidence. The present report is intended as a practical handbook which will be useful to investigators in the field. The book consists almost entirely of tables of chemical composition, but the text and bibliography are adequate to permit ready understanding and utilization of the tables. The type is large enough to be easily legible and accurately transcribed. The binding is of good quality.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MARRIAGE AND EMPLOYMENT IN SERORESISTANT SYPHILIS

***To the Editor:*—A man aged 22 was rejected by the army four years ago because of a positive Kahn test (1 plus). His family physician also found a positive serologic test. The patient was hospitalized and given over 2 million units of penicillin, after which the blood Kahn test was still positive. Later he was given "eighty shots" weekly. The Kahn test remained positive. Spinal fluid examination revealed no central nervous system involvement. Serologic tests on other members of the family were negative. The patient does not give history of initial or secondary lesions and has always been in sound health. Because of state laws he is unable to obtain work or to be married because of the positive serologic test. What course should be taken in this case? Has he ever had syphilis? Should he receive further treatment of a more intensive nature? If he is "Wassermann Fast"—what can be done legally to clear him for work and marriage?** Andrew L. Laurie, M.D., Mount Dora, Fla.

ANSWER.—The interpretation of an unexpectedly positive blood serologic test found in the course of routine examination is always a matter of some difficulty. On the basis of general probability, syphilis is much more likely than a biologic false positive serologic test due to some other condition. In general it may be safely assumed that, excluding technical error (which is of course excluded in this case by virtue of the fact that the blood test has been repeatedly positive over a four year period), 95 to 98 per cent or more of all such positive tests are due to syphilis. In this case congenital syphilis seems to be ruled out by the negative examination of members of the family and by the probable absence of stigmas in the patient himself, who is said to be "in sound health."

The fact that the serologic test for syphilis has been positive for four years is strongly in favor of syphilis and strongly against a biologic false positive reaction. The false positive tests due to other conditions usually persist for only a short time. Some further information might have been gained if the tests had been quantitatively titered before any treatment was given since, by and large, false positive tests tend to be lower in titer as contrasted with those due to syphilis.

Has the patient in question ever had the opportunity to acquire syphilis by means of sexual exposure or kissing? Symptomless infection is of course common, either with the complete absence of primary or secondary lesions or with such trivial or insignificant lesions that they are overlooked or misinterpreted by the patient or his physician.

On the basis of the information given the patient may be regarded as having seroresistant latent syphilis and his future course should be guided by the discussion in Moore, J. E.: Seroresistance (Wassermann Fastness) in Syphilis: A Discussion for the Patient (*Am. J. Syph., Gonor. & Ven. Dis.* **30**:125 [March] 1946). The inquirer may obtain a reprint of this paper on request, and both he and the patient should read it.

The inquirer almost certainly misinterprets the state law. Neither in Florida nor in any other state in the Union does a positive blood test bar a person from employment or marriage. The premarital blood test laws provide only that a patient with infectious syphilis may not marry. This patient, with an infection of at least four years' duration and with treatment already amounting to a year and a half of metal chemotherapy plus a course of penicillin, is not infectious. A few unenlightened companies may refuse to employ seropositive persons, but this has nothing to do with the law, and the situation may usually be straightened out either as to marriage or as to employment by a letter from the physician to the appropriate authority describing the situation and certifying as to the patient's noninfectiousness and eligibility for marriage or employment. Legal steps are not necessary.

INFLUENZA VIRUS VACCINE

***To the Editor:*—Please discuss the effectiveness of influenza virus vaccine prepared by the calcium phosphate adsorption method and by the red cell elution method.** Robert J. Ralston, M.D., Holyoke, Colo.

ANSWER.—Influenza virus vaccine prepared by adsorption on calcium phosphate should be as effective as that prepared by the red cell elution method if the virus content and stability of the preparation are insured. There is insufficient evidence in the literature to warrant the assumption that there is an adjuvant effect in man.

TREATMENT OF CHARLEYHORSE

***To the Editor:*—1. What is the proper treatment for an ordinary charleyhorse or muscle cramp? 2. What is the physiologic explanation of a cramp? 3. Is massage contraindicated?** Harry W. Orris, M.D., Brooklyn.

ANSWER.—1. A charleyhorse is not a muscle cramp. The proper treatment for a charleyhorse, which is an injury to a muscle, usually the quadriceps femoris, depends on when the patient reports for treatment. The injury consists first in a contusion to the muscle by a direct blow, which results in a hematoma as a rule. Later this hematoma may organize into a myositis ossificans, forming soft bone in the muscle. This bony formation tends to grow larger and organize to produce real hard bone.

In the acute stage at the onset of a charleyhorse the leg should be packed in ice about the injured area and held quiet for half an hour to an hour. In the acute stage subsequently for about six weeks (*a*) the leg should be placed at rest in a cast or splint (preferably a cast for "children, athletes and idiots") and kept quiet for ten days, the patient continuing to wear the cast for six weeks; (*b*) diathermy, long wave treatments, should be given daily (the cast may be split for this); (*c*) heat or contrast baths should be given; gentle motion should be given every few days to prevent stiffness. If bone forms and causes pain or loss of function after six weeks, removal of the excess bone should be considered. This should not be done until the bone has become organized and is not growing in size as determined by roentgenograms. For a review of this condition see the article "Myositis Ossificans" by Marcus H. Hobart (*Am. J. Surg.* **34**:227 [Nov.] 1936).

2. The physiologic explanation for a cramp may not be entirely clear. There has probably been an overstimulation of the muscle fibers or the motor nerve, resulting in muscle and nerve fatigue. There may be a reduction in oxygen to the muscle cells and an excess of lactic and other acid or waste products.

3. Massage is contraindicated for a charleyhorse or muscle injury, especially at first, but is not contraindicated for a cramp, which is an entirely different pathologic entity.

ALUM PRECIPITATED AND PLAIN TETANUS TOXOID

***To the Editor:*—I am encountering veterans of both the army and navy who are in need of prophylactic measures against tetanus. I am under the impression that men who served with the navy were immunized against tetanus with the alum precipitated toxoid and those of the army with the plain toxoid and that an additional booster dose of either will suffice to protect the patient in the event of an injury. Can a booster dose of the alum precipitated toxoid be given to an army veteran who had the series of plain toxoid? Why is alum precipitated toxoid favored in civilian practice when plain toxoid does not produce a tender lump at the injection site as is seen with the use of alum precipitated toxoid?**

Glenn T. Howard, M.D., Pearsall, Texas.

ANSWER.—The navy has employed alum precipitated tetanus toxoid and the army has used the plain (fluid) tetanus toxoid.

Under ordinary circumstances a booster dose of either plain tetanus toxoid or of alum precipitated tetanus toxoid will suffice to protect a person in case of injury. The two types of tetanus toxoid are interchangeable, since the only difference consists in the presence of alum in the one and its absence in the other.

Because of the great variability in the duration of demonstrable (titrable) antitoxic immunity against tetanus (three or more months to five or more years) it is desirable that recall (booster) injections be administered in the presence of injuries considered likely to lead to the development of clinical tetanus. There are circumstances under which antitetanic serum (passive immunization) has been recommended instead of a booster dose of tetanus toxoid (active immunization). In the presence of serious hemorrhage, poor general health, diseases of a debilitating nature, severe or multiple injuries or delay in the injection of tetanus toxoid, the use of adequate doses of antitetanic serum (10,000 or more units) is justified. There is a definite difference of opinion concerning this particular problem, so that failure to employ tetanus antitoxin under these circumstances cannot be interpreted as an act of negligence.

It is supposed that basic immunity, the ability of the body to respond to a booster dose of tetanus toxoid, is lifelong. The available data indicate that a person will produce tetanus antitoxin in response to a booster dose of tetanus toxoid as long as five to six years after initial immunization with tetanus toxoid. The response is characterized by four features: 1. Acceleration: A high level of antitoxin appears in seven days or less, thus providing adequate immunity in the presence of short incubation periods. 2. Augmentation: The antitoxic level after the booster dose is remarkably increased, sometimes to levels as high as fifty to one hundred times those present at the time of recall injection. 3. Prolongation: The duration of antitoxic immunity is more persistent than that evoked by the previous injections.

4. Facilitation: The body responds to minute doses of tetanus toxoid. Thus, a recall injection of but 0.1 cc. elicits a satisfactory immunologic response. The practical significance of this phenomenon ("hair trigger reaction") resides in the fact that the employment of minute booster doses of tetanus toxoid minimizes the incidence of discomforting local and constitutional reactions among those repeatedly subjected to injuries which require the use of booster injections of tetanus toxoid. However, at present it is customary to employ the volume of tetanus toxoid recommended by the manufacturer.

Although it is the theoretical consensus that alum precipitated tetanus toxoid is antigenically superior to the fluid toxoid, fluid toxoid is a satisfactory immunologic agent, as evidenced by its successful use in the United States Army. Sensitivity reactions are reported to be of lesser incidence and severity with alum precipitated tetanus toxoid than with plain (fluid) toxoid, although adverse reactions are infrequent with the latter. One advantage of alum precipitated tetanus toxoid is that two doses are usually sufficient to induce immunity, whereas three injections of the fluid toxoid are commonly recommended.

Plain tetanus toxoid is now commercially available.

ELECTRIC SHOCK AND VARICOSE VEINS

To the Editor:—A man received second degree burns of the soles and of the left arm and developed varicose veins of both legs following an electric shock from a 220 volt circuit, 30 amperes. Varicose veins first appeared below both knees from sixty-five to seventy-two hours after the electric shock and have extended upward above the knee on the left leg. Could electric shock from such a circuit, which was severe enough to pull the patient down and require the assistance of fellow employees to break the circuit, be considered a factor in the development of the varicose veins? Available evidence indicates that the man did not have varicose veins prior to the accident.

Francis E. Sultzman, M.D., Hannibal, Mo.

Answer.—There is at least one reported case in which occlusive phlebothrombosis in a leg was thought to have been caused by an electric shock. According to Homans the compensatory dilatation of collateral venous channels following an occlusive phlebothrombosis may lead to permanent varices. Thus the possibility that an electric shock may result in the development of varices cannot be categorically denied.

It is a fact, however, that there is neither experimental nor reliable clinical evidence to indicate that persistent phlebectasia has been caused by electric shock. It is also true that in the case of spontaneous varices the transition from a nonsymptomatic to a symptomatic phase of the disease may be so abrupt that the patient is unaware of his disorder until within a few days of the time that he seeks medical advice.

In view of these facts the existence of a cause and effect relationship between the electric shock and the development of varicose veins in the case described in the query appears to be improbable but not impossible.

CENTRAL CHOROIDITIS

To the Editor:—1. Is there any treatment for the visual disturbances in central choroiditis, and why does it occur only at intervals? 2. If there is loss of central vision, is any treatment necessary in cases not due to syphilis? 3. Has undulant fever proved to be a cause of central choroiditis?

M.D., Arizona.

Answer.—1. Central choroiditis is a term rather loosely applied to all sorts of circulatory, inflammatory, degenerative and atrophic changes occurring in the region of the macula. The variety in which visual disturbances come only at intervals is probably due to central angiospastic changes or to the presence of an infective focus occurring intermittently in the presence of ocular tissue allergy. Treatment in the former is directed toward elimination of all toxic factors, a correction of metabolic disorders and study of the reactions of the peripheral circulation with a view to increasing its stability and maintaining a dilatation of the smaller vessels. Intravenous injections of typhoid vaccine (10 to 25 millions) or papaverine hydrochloride ¼ grain (15 mg.) or nicotinic acid by mouth are often effective. Sedatives may help hyperemotional patients. Tobacco and exposure to cold and fatigue should be avoided. In the inflammatory type the most important element in the treatment is to determine and eliminate the etiologic factor. In some instances desensitization to tubercle protein or streptococcus toxin is indicated. In the more chronic stages iodides may aid the healing process. Telescopic lenses may provide reading vision even in some old healed lesions.

2. Even though central vision has been lost, particularly if only unilaterally, every care should be taken that damaging repetitions do not occur.

3. Undulant fever is accepted as a cause.

ALOPECIA AND PREGNANCY

To the Editor:—A quintipara who has had normal pregnancies and rapid deliveries has lost hair from her head with each pregnancy. At the present time she is nearly bald. In the books available alopecia with pregnancies is not mentioned. What are the prognosis and treatment?

M.D., Michigan.

Answer.—The information furnished is too incomplete to tell what kind of alopecia this woman has. Does hair regrow between pregnancies? Is the hair loss diffuse or in patches? If the latter is the case, then she probably is suffering from alopecia areata. The prognosis is relatively good if she is less than 35 years of age and if the hair has regrown readily before. If the alopecia is of the diffuse variety and has been progressive without attempts of regrowth, then the prognosis is indeed bad. It is most likely that the hair loss is instigated through endocrine changes, probably initiated by the pituitary. Pituitary extract may be of value in certain types of alopecia and may be tried. The patient should be thoroughly studied. Thyroid medication may be indicated. Local therapy will probably not be effective, although ultraviolet exposures to the scalp and stimulating applications may be tried. For the latter the following prescription is useful: tincture of cantharides 8 cc., tincture of capsicum 1 cc., alcohol 45 cc. and rose water to make 150 cc.

OCULAR VERTIGO

To the Editor:—A woman aged 67 becomes intensely dizzy with a tendency to falling forward whenever she watches passing cars. Complete clinical and laboratory examination have been normal except for hypertension with blood pressure of 190/110 and an irritable colon. Labyrinth studies have been normal. Please discuss the physiologic mechanism of the vertigo in this patient.

George Vash, M.D., Chester, Mass.

Answer.—The patient described in the query seems to have normal physiologic vertigo known as ocular vertigo. This type of vertigo is usually associated with nystagmus and is analogous to the dizziness that appears in many people when they gaze at telegraph posts while on a moving train. There may be another type of vertigo, described by Otfried Foerster of Breslau, due to a lesion of the cerebral cortex with stimulation of the superior lip of the interparietal sulcus of the brain.

FALSE REACTIONS IN TESTING URINE FOR SUGAR

To the Editor:—What drugs cause false reactions in testing for sugar? How much aspirin will cause it?

M.D., Illinois.

Answer.—None of the drugs usually employed therapeutically, including acetylsalicylic acid, should in themselves produce falsely positive reactions for sugar in urine, although some drugs, such for example as camphor, chloral hydrate, morphine and many aromatic alcohols or phenols, are eliminated as conjugate glucuronates, and the glucuronates reduce the copper reagents. The administration of some drugs also results in a low grade glycosuria. Ether anesthesia causes an increased excretion of ascorbic acid, which reduces the copper reagents, as does homogentisic acid, found in the urine in alkaptonuria.

At the present time Benedict's qualitative reagent (The Journal, Oct. 7, 1911, p. 1193) is the copper reagent of choice, since it is more specific and sensitive for sugar in urine than the older Fehling's and Haines's solutions and is not reduced by creatinine, uric acid, chloroform or the simple aldehydes.

TREATMENT OF FACIAL ANGIOMAS

To the Editor:—With regard to the query in The Journal July 6, 1946, page 873, concerning the treatment of facial angiomas in infants, I would protest the answer and advice given. The angioma described will cease growing before the child is 10 months of age, and it will involute spontaneously before the child is 5 or 6 years of age. There is no justification for the treatment of the described angioma. It is regrettable that the majority of dermatologists adhere rigidly to the old concepts of treatment of angiomas. The pediatricians must familiarize themselves with the newer concepts and adopt a more critical attitude toward the diagnosis and treatment of vascular nevi.

KERATOSIS OF THE LARYNX

Chairman's Address

LOUIS H. CLERF, M.D.
Philadelphia

Epithelial hyperplasia of the larynx may assume all gradations from simple diffuse thickening in chronic inflammation to localized keratosis, papillomatous masses which fill the larynx or carcinomatous ulceration with extensive invasion. As a result, difficult problems in diagnosis are encountered.

Localized areas of thickening of the epithelium which appear as single or multiple chalky white elevations on the upper surface and edge of one or both vocal cords usually with involvement of the membranous portion are not uncommon. These have been designated as keratosis, hyperkeratosis, leukoplakia, pachydermia laryngis or by other terms by laryngologists and pathologists, and by some these terms appear to be used synonymously; others consider them as distinct and different entities.

Pachydermia laryngis as described by Virchow referred to thickening of the posterior wall of the larynx and the posterior half of the vocal cords. It was observed in alcoholic addicts or excessive voice users, as street hawkers. The involved areas are grayish white and exhibit proliferation of the superficial epithelium as well as thickening of the basal layers, so that the histologic appearances often suggest papilloma.

Keratosis, hyperkeratosis or leukoplakia is primarily a localized benign hyperplasia of epithelium which does not invade the submucosa. The whitish surface which may appear smooth or granular or may exhibit elevations or villous projections stands out in contrast to the surrounding cordal mucosa which often is the seat of a chronic inflammatory process.

CAUSES

The causes of keratosis are still in the realm of speculation. It is observed more commonly in male adults who are addicted to excessive smoking, particularly of cigarets. Although I am convinced that this is a predisposing factor, it is obvious that such a statement lacks definite proof. Excessive use of the voice and alcoholism do not appear as important etiologic factors. The incidence of syphilis does not appear greater among patients with keratosis. The frequent association of keratosis with chronic laryngitis suggests long-continued irritation as a predisposing cause. Studies in food deficiency diseases indicate that keratosis is often a manifestation. It has long been observed that keratinization of the skin is related to disturbances in vitamin A metabolism. Whether this is the result of an inadequate diet or failure to assimilate vitamins cannot always be accurately determined. Wolbach and Howe[1] have reported changes in epithelium which followed deprivation of fat soluble vitamin A in experimental studies on rats. These changes consisted of the substitution of stratified keratinizing epithelium for normal epithelium in various parts of the respiratory tract and elsewhere. There is clinical evidence to substantiate this view.

Graham[2] reported his observations on the effects of a high vitamin diet in a case of keratosis of the larynx. In spite of a histologic diagnosis of carcinoma there was observed remarkable regression of the entire lesion as soon as attention was paid to the patient's diet.

In discussing keratosis in general, Reimann[3] considered it "to be primarily a disease of shedding of the superficial layers. These cells do not differentiate as do normal cells but stick together, pile up and produce the islands we call keratinized because of the excess of keratin in the cells." The occasional appearance of villous projections on an area of keratosis has suggested a mycotic origin, since these appear similar to the mycelial filaments observed in infections by the leptothrix group. Histologic study of the white villi in keratosis shows cornification of epithelium. The rare occurrence of a leptothrix is an incidental observation.

Although excessive use or abuse of the voice may lead to localized keratosis seen as vocal nodules or to diffuse polypoid hyperplasia of the vocal cords, the clinical and histologic appearances are not those of keratosis (fig. 1).

While there is definite overgrowth of epithelium, the basement membrane is usually even, and the submucosal tissues exhibit little or no inflammatory reaction and are the seat of edema. In the forms of keratosis appearing on the surface of a vocal cord there is commonly observed a variable amount of inflammatory reaction in the submucosa. This has caused much comment, and the question has arisen whether it is of prognostic import. New and Erich,[4] Graham,[2] Bucher[5] and others have directed attention to this pronounced subepithelial inflammation (fig. 2).

PRECANCEROUS LESIONS

Clinical observations have long shown that many tumors arise from tissues that were once normal, and various forms of chronic inflammatory changes are

observed to precede the appearance of many tumors. This brings up the interesting and much debated question of whether keratosis or any form of benign epithelial hyperplasia may be considered as a so-called precancerous lesion.

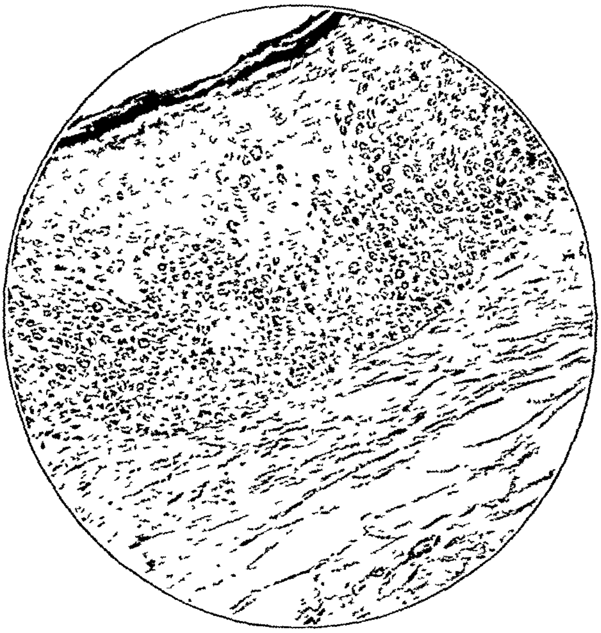

Fig. 1—Photomicrograph (× 200) of a hyperplastic vocal cord. The epithelium is greatly thickened, but the basement membrane is regular. There is definite edema and fibrosis with a few inflammatory cells in the submucosal layer.

In chronic inflammatory lesions of the larynx in which there develops decided hyperplasia of the epithelium in an effort at repair, this hyperplasia and this irregularity frequently suggest early malignant changes. The term precancerous has been applied to this type of lesions by many writers, and there undoubtedly is some justification for its use by laryngologists when they have under consideration certain benign lesions that have undergone malignant changes. As stated by Crawford[6] "in the histologic examination of tissue in a number of these cases it was impossible to predict with any degree of certainty in which cancer would develop and in which recovery would occur." It is, of course, obvious that the pathologist cannot anticipate by a study of cells that a benign lesion will become malignant. Coplin[7] appropriately stated that "histology rarely, if ever, tells us what a cell is going to do before it does it, although many of us are constantly deluding ourselves into the belief that we can deduce the future of a cell from a study of the past or present or both."

In Graham's[2] case of keratosis there was histologic evidence of carcinoma. Morrison[8] reported a case of keratosis in which a carcinoma apparently developed as a single small island of malignant cells in the subepithelial layer beneath a mucous gland. A satisfactory result was secured by laryngofissure. New and Erich[4] reported 10 cases, in 2 of which there developed squamous cell carcinoma. The carcinomatous lesions were definitely localized in both of these cases. The carcinoma was discovered histologically, and the authors emphasized the importance of thorough microscopic examination. Eggston[9] stated that keratosis should always be considered a precancerous lesion. After many years of experience in a study of the pathologic changes observed in these cases he found in many instances that they sooner or later, after several biopsies, had grown to be frankly epidermoid carcinoma. This may occur in a matter of months or even years. He expressed his conviction that keratosis of the larynx should be treated as a precancerous lesion and preferably by surgical removal. Reimann[3] believed that many of these lesions are precancerous but that it is impossible to say which of a group of such keratoses will turn into cancer. In the interests of cancer prevention, if all keratoses were removed completely none could develop into carcinoma. While it is not known whether carcinoma develops from purely local causes or whether, in addition, there must be a constitutional or genetic influence, he stated that in the case of certain extremely powerful carcinogens, probably the local influence far outweighs any other; but in the case of keratoses in general, there is certainly a constitutional predisposition. In discussing keratosis, the Jacksons[10] stated that "so far no case has shown malignant developments."

PATHOLOGY

From the pathologist's point of view, Bucher[5] described the whitish elevations on the vocal cords as small masses of hyperplastic squamous epithelium, which at times are suggestive of papilloma, but the usual characteristic arrangement is lacking. The basement membrane is commonly regular, sometimes pushing into the submucosa in small irregular projections so that it becomes difficult to decide whether there is infiltration or whether the process is merely a part of the hyperplasia. In most instances a good basal layer of epithelium is observed. The keratinization varies

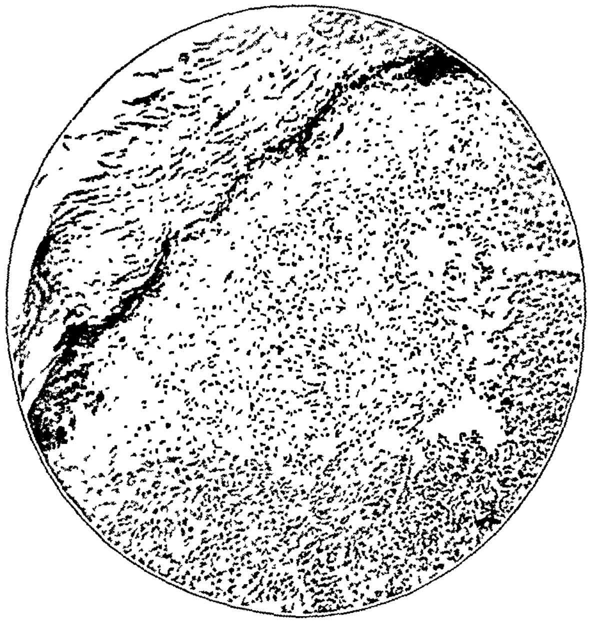

Fig 2—Photomicrograph (× 100) of section with definite epithelial hyperplasia and keratinization. The basement membrane lacks clear definition, the basal cells are deeply staining; the submucosal layer exhibits pronounced inflammatory changes. This type of keratosis is extremely suggestive of early carcinoma.

in different persons. The changes in the submucosal tissues are important and consist in infiltration with cells of inflammatory origin (namely, lymphocytes, monocytes and plasma cells), the presence of numerous thin-walled vessels and edema with a variable amount of fibrosis. Occasionally there are deposits of blood pigments. The older pathologists referred to this type of keratosis as pachydermia verrucosa. In reviewing histologic slides in a large number of cases of keratosis over many years, particularly in those in which frequent biopsies have been performed, it is his belief that lesions which show considerable inflammatory changes and great irregularity of the basement membrane should be dealt with in the same manner as early carcinoma.

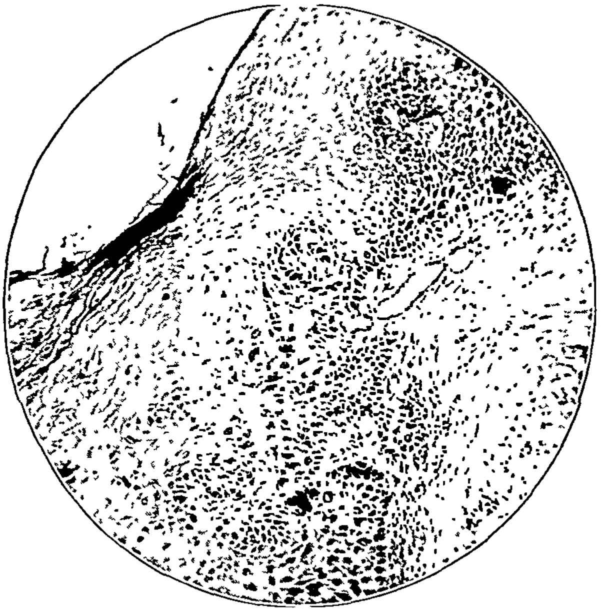

Fig 3.—Photomicrograph (× 100) of keratotic tissue reveals thickened epithelium with projections extending into the submucosal layer. The basement membrane, however, appears intact. Moderate inflammatory changes are present in the submucosa.

SYMPTOMS

Although the laryngoscopic appearances and the extent of the keratotic lesions may vary, there is commonly but one symptom, namely, change in the voice. This may consist only of slight huskiness, or the voice may be hoarse. Occasionally there may be clearing of the throat.

TREATMENT

In an experience covering a considerable number of cases I have been impressed with the fact that it is difficult if not impossible to prognosticate the outcome in any 1 case. Irrespective of the plan of therapy employed, frequent examination of the larynx is imperative because of the rapid recurrence of simple keratosis in some patients and changes in others that suggest the occurrence of carcinoma. In certain cases, the patients recover on a regimen of no smoking, vocal rest, vitamin therapy and the removal of keratotic material by the use of cupped forceps or other appropriate means. In another group these therapeutic measures appear inadequate, and masses of keratosis reappear in spite of frequent removals without, however, any histologic evidence of carcinoma. In such cases it may be necessary to strip the vocal cords of their mucosal and submucosal coverings as described by Loré[11] and Putney and Clerf.[12] In a third group the clinical and histologic appearances are so suggestive of carcinoma that laryngofissure appears to be indicated, although study of the material removed at operation may fail to reveal any evidence of carcinoma; and, lastly, there is the group in which at some time or other during the course of the disease carcinoma develops in or about the site of the keratosis. Cases illustrating these groups will be cited.

REPORT OF CASES

Cases That Responded to Conservative Therapeutic Measures

A man aged 52 was observed eleven weeks after the onset of hoarseness, subsequent to an acute infection of the upper respiratory tract. He was a moderate smoker of cigarets. Mirror laryngoscopy revealed extensive keratosis which involved the upper surface and edge of the right vocal cord Direct laryngoscopic removal of keratotic areas was performed and all the material was examined histologically. This revealed hyperplastic epithelium with moderate inflammatory changes in the submucosa. There was no evidence of carcinoma (fig. 3). The patient was placed on a regimen of no smoking and moderate use of his voice and given large doses of combined vitamins. A second laryngoscopy was necessary to remove additional keratotic material. The patient made a satisfactory recovery, and there has been no recurrence of keratosis for over eight months.

Cases Requiring Frequent Removal of Mucosal and Submucosal Tissues

A man aged 48 was first examined in September 1941. He had been hoarse for one year after a cold. He was an excessive smoker of cigarets and used alcohol moderately. Mirror laryngoscopy revealed a whitish granular-appearing lesion on the upper surface of the anterior half of each vocal cord. Both cords exhibited definite inflammatory changes and the edges appeared irregular, suggestive of probable neoplastic changes. Biopsies were performed from both cords. There was pronounced hyperplasia of epithelium with inflammatory infiltration of the submucosa (fig. 2). The patient was advised to discontinue smoking and placed on combined vitamin therapy but failed to cooperate. A total of fourteen removals of keratotic material were performed over a period of four and a half years, and all the tissue was examined histologically. On five occasions the pathologist reported that the changes were extremely suggestive of early carcinoma, but no positive diagnosis could be made. In February 1944, two and one-half years after treatment was begun, the left cord remained free of keratosis, and when the patient was last seen in April 1946 there still appeared a small patch on the right vocal cord. At no time after the first examination did the clinical appearances suggest carcinoma, and for that reason it was decided not to carry out any radical surgical procedure, for the extent was such that both vocal cords would have had to be removed. The patient now is following the prescribed plan of therapy, and the prognosis appears good

Cases Not Frankly Carcinoma but Requiring More Radical Therapeutic Measures

This group is represented by 2 men, aged 48 and 67 respectively, who had unilateral keratosis involving the anterior half of the right vocal cord The lesions appeared nodular with decided inflammatory changes and were suggestive of carcinoma. The biopsy report was keratosis with many mitotic figures and pronounced submucosal inflammation Although a positive histologic diagnosis of carcinoma could not be made, the lesions nevertheless appeared clinically to be suggestive of carcinoma, and for that reason laryngofissure was performed. The membranous vocal cord was removed in each case and studied histologically, but in neither case was there evidence of carcinoma. These patients developed excellent voices, since removal of the cord did not include the perichondrium, and a satisfactory vocal band ultimately developed.

Cases of Keratosis Which Ultimately Exhibited Histologic Evidences of Carcinoma

This group consisted of 4 cases in which the patient's disease had been under treatment for prolonged periods as keratosis but ultimately developed into carcinoma. In 3 cases laryngofissure was performed and in 1, a laryngectomy.

Case 1.—A man aged 55 was first observed in February 1938. There was a history of keratosis with hoarseness of two years' duration. At the time of observation in 1938, there was an area of keratosis on the upper surface of the right vocal cord, anteriorly, with a larger patch on the upper surface of the left vocal cord, involving its middle and anterior thirds. The histologic report was hyperplasia and keratosis of the epithelium with submucosal inflammation. There was no evidence of carcinoma. The patient returned to his physician, a laryngologist, who kept him under observation, and no change was observed until the fall of 1942, three and one-half years later, when a papillary lesion appeared on the left vocal cord. Biopsy revealed a squamous cell carcinoma. The lesion was small and was removed by laryngofissure in November 1942. The patient has had no recurrence of carcinoma or keratosis since that time.

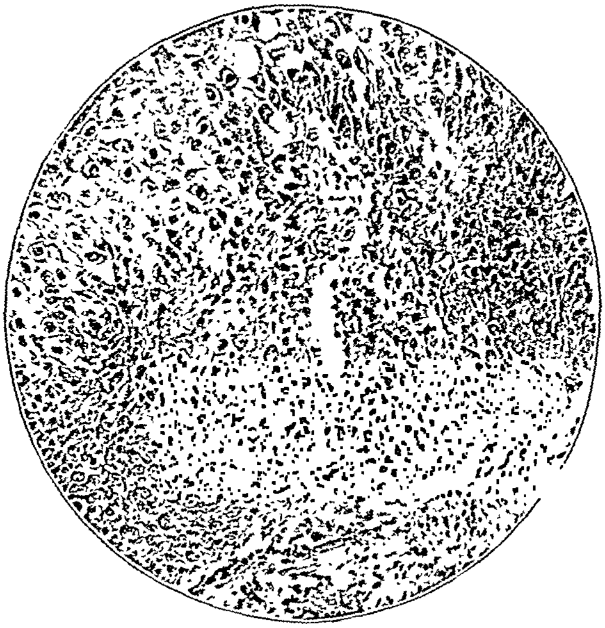

Fig. 4.—Photomicrograph (× 200) revealed definite epithelial hyperplasia, deeply staining nuclei and occasional mitosis. The basement membrane was only fairly well defined. There was considerable submucosal inflammation. Over three years later a small area of carcinoma was discovered by biopsy.

Case 2.—A man aged 53 was first observed in August 1943. He was an excessive smoker of cigarets. A diagnosis of chronic laryngitis had been made over two years previously, and he was kept under observation. When he was examined in 1943, there was a white lesion with small villous projections on the anterior half of the right vocal cord. A histologic diagnosis of keratosis was made. There was no evidence of submucosal invasion. There were many mitotic figures, and there was submucosal infiltration with round cells. Dr. Bucher who examined the tissue stated that while the histologic appearances were those of keratosis the extent of involvement and the associated submucosal inflammatory changes together with the occurrence of mitotic figures suggested that this was a borderline case (fig. 4). The patient discontinued smoking and was placed on vocal rest. In April 1946, over three years later, there was an increase in hoarseness, and a granular nodule was found on the right vocal cord in its anterior third. The biopsy report was squamous cell carcinoma, intermediate grade. The lesion was removed by laryngofissure.

Case 3.—A man aged 38, an inveterate cigaret smoker, had been hoarse for eight months. On examination in October 1942 there was observed keratosis on the upper surface and edge of each vocal cord, anteriorly, extending into the anterior commissure. There was definite heaping up of keratotic material on the right cord suggestive of a nodule. A biopsy revealed no carcinoma. The epithelium was thickened, but there was little submucosal inflammation. Five removals of keratotic material from both vocal cords were performed during the succeeding eight months. All the tissue was negative for carcinoma. For a time there was no recurrence of keratotic material, but in January 1944 there was a recurrence of a large mass on the upper surface of the left vocal cord and of a smaller mass on the right cord. Biopsy of the left cord revealed carcinoma. A laryngofissure was performed and both vocal cords were removed.

Case 4.—A man aged 46 was first examined in August 1943. He had been under observation and treatment elsewhere for three years. Various diagnoses had been made, including keratosis, fungus infection and carcinoma. He had been given large quantities of vitamin A with some resultant improvement in the voice but no apparent change in the larynx. On examination a large granular white area was observed on the edge and upper surface of the right cord. The left cord was normal. The appearances were suggestive of carcinoma, but a biopsy was negative. Additional tissue was removed with negative findings. Because of the apparent lack of improvement and the duration of symptoms for more than five years the patient changed physicians, and the larynx was not examined for one year. He returned in May of 1946 with an extensive ulcerated lesion involving the entire right vocal cord. A biopsy revealed a squamous cell carcinoma, and it was necessary to perform a laryngectomy.

COMMENT

While keratosis is often observed in association with carcinoma of the larynx, the 4 cases cited herein exhibited evidences of keratosis of the larynx for two to four and one-half years from the time that I first observed them until a diagnosis of carcinoma was made; and, in addition, it was known that keratosis was present for eight months in 1 case, two years in 2, and three years in 1 case before the patients were examined by me. It is evident therefore that I was dealing with keratosis in the beginning and that carcinoma developed later. While there is no evidence to indicate that the keratotic cells ultimately assumed a malignant character, there is justification for the statement that patients with keratosis of the larynx should be carefully observed because in a certain proportion of cases carcinoma will develop.

CONCLUSIONS

Keratosis of the larynx is a relatively common benign condition. It is more often observed in adult males and particularly in those who smoke excessively.

There is experimental and clinical evidence to suggest that keratosis of the larynx is a manifestation of a metabolic or a food deficiency disease.

Clinical observations indicate that although keratosis per se is benign, there are a certain number of keratoses that either become carcinoma or predispose to its development.

While the outstanding changes observed histologically in these cases are epithelial hyperplasia and submucosal inflammation, it is impossible for the pathologist to anticipate in any given case that cancer will develop, although at times it is difficult to differentiate between early carcinoma and simple keratosis.

Patients with keratosis of the larynx should be kept under close observation; the involved areas should be removed and all tissue examined histologically. If there is any question of the occurrence of carcinoma, more radical surgical intervention is indicated.

VENOUS THROMBOSIS

ALTON OCHSNER, M.D.
New Orleans

The significance of venous thrombosis is exemplified by the interest which is shown in this subject by physicians in general. The fact that on the present program of the Section on Surgery, General and Abdominal, of the American Medical Association three titles are concerned with the subject of venous thrombosis is indicative of the importance of the condition. The significance of venous thrombosis is further demonstrated by the observations in McCartney's[1] autopsy cases. In 25,771 necropsies performed at the University of Minnesota from Jan. 1, 1919 to Dec. 31, 1938, death was due to pulmonary embolism in 687 (2.67 per cent). Even more remarkable was the disclosure that in 107 of the cases embolism had already occurred, or a thrombus existed which could have produced a fatal embolism. Venous clotting is of importance not only because of the symptoms which are associated with certain types, but also because of the possible sequelae, such as the persistence of symptoms subsequent to thrombophlebitis or even the occurrence of death from pulmonary embolism.

Clinical experience and experimental observations have resulted in a conviction that one cannot consider all venous thromboses as the same type of lesion, but that one must differentiate between two types which are different etiologically, symptomatically, prognostically and therapeutically. Unless there is a differentiation between these two types of venous thrombosis, the therapy is likely to continue to be unsatisfactory. In 1939 DeBakey and I[2] emphasized the importance of differentiating thrombosis associated with an inflammatory process of the vein from that of the bland thrombus occurring in a vein in which there is no inflammatory lesion. At that time the suggestion was made that in addition to considering thrombophlebitis, which designated that condition in which there is an inflammatory process involving the vein associated with thrombosis, the physician must consider phlebothrombosis, which "may be defined as partial or complete venous occlusion by an intravascular clot which is unassociated with inflammation, the clot being loosely attached to the vein wall." This differentiation has been emphasized in subsequent publications[3] and has been generally accepted, although there are a few who have not been willing to accept the designation of phlebothrombosis or to admit that such a condition occurs, maintaining that in all instances an underlying inflammatory process is responsible for the development of thrombosis in the patient. Jensen[4] expressed the opinion that phlebothrombosis does not occur except after trauma and will occur only in incised, lacerated or abraded wounds. On the other hand, Hunter and his associates[5] expressed the opinion that phlebothrombosis and thrombophlebitis are two distinct entities. Their conclusion was based on a careful anatomic investigation and was not a mere clinical presumption, which is apt to be inaccurate. In 350 unselected autopsies, the veins of the calf muscles were examined in 209 instances. Venous thrombosis was found in 185 cases, and in only 17 instances (9.1 per cent) was there evidence of a phlebitis; in the remainder there was no evidence of an inflammatory process, although a thrombus was present in the veins. These authors concluded that as far as thrombosis of the veins of the calf muscles is concerned, inflammation of the vein, i. e. phlebitis, has little to do with the production of the clot.

The mechanism of the clot formation in the two types of venous thrombosis, thrombophlebitis and phlebothrombosis, is entirely different. In thrombophlebitis, as a result of the inflammatory process of the vein wall, there are changes within the vascular endothelium which predispose to clotting. This is similar to the process that occurs when a sclerosing agent is introduced into a varicosity. In the spontaneously occurring thrombophlebitis, the inflammatory process is usually the result of involvement of the vein secondary to perivenous lymphangitis, the micro-organisms being carried to the vein through the lymphatic system. In some instances there is evidence that the changes in the vascular endothelium are not due to bacterial invasion but may be caused by toxins or allergic sensitization (Turnbull[6]). In thrombophlebitis, unless it is associated with a severe suppurative process such as lateral sinus thrombophlebitis or portal thrombophlebitis, the femoral and iliac veins are usually the ones involved. Since the thrombus in thrombophlebitis is the result of inflammatory change in the vein wall, particularly the endothelium, the resultant clot is either a white or a mixed thrombus and is firmly attached to the vein wall. For this reason, with two possible exceptions, thrombophlebitis is not associated with embolism because the clot is attached and cannot become detached. The first of the two exceptions is the possible formation proximal to the area of thrombophlebitis of a bland thrombus, or coagulation thrombus, which is not attached and which can become detached. This is usually of little significance, because it is a relatively short clot, and if it did become detached it would produce a small infarction. The formation of such a clot should not be permitted, and it can be prevented by mobilization of the involved extremity during the treatment of the thrombophlebitis. The other exception is suppurative thrombophlebitis in which, as a result of liberated proteolytic ferments, the fixed clot can become liquefied and permit fragments to break off with the resultant production of septic emboli. This is usually observed in patients with severe pelvic infections and is generally subsequent to criminal abortion. In this instance, the detachment of the thrombus is the result of a suppurative process and does not result because the clot was detached. In contrast, the mechanism of the formation of the thrombus in phlebothrombosis is entirely different. There is no inflammatory process

in the vein wall, and the clot is the result of two factors, the increased coagulability of the blood and the slowing of the blood stream. The clot which is formed is a red or coagulation thrombus similar to the clot which occurs in a test tube when blood is withdrawn from the vascular system. It is only loosely attached to the vein wall; it can become detached relatively quickly, with the same ease as the coagulum which appears in the test tube can be detached from the walls of the tube when the tube is inverted. These thrombi, as has been shown repeatedly by autopsies,[8] usually originate in the veins of the calf muscles or in the veins on the plantar aspect of the foot but may extend up into the deep veins of the thigh and pelvis. They are extensive thrombi and, since they are not firmly attached, are of real potential danger, because of the possibility that they will be detached and carried through the venous system to the heart and lungs, thereby producing varying grades of infarction from relatively insignificant peripheral infarction to total occlusion of both pulmonary veins, with sudden death. It is possible, if for some fortunate reason the coagulation thrombus in phlebothrombosis does not become detached, that sufficient inflammatory reaction will occur in the intima of the vessel and firm attachment will ultimately take place. Bauer[9] expressed the belief that this process begins soon after the formation of the thrombus. I am of the opinion, however, that it is a late and infrequent phenomenon and should not be anticipated.

Although the mechanism for the development of the thrombus in thrombophlebitis is readily understandable, the mechanism for the development of the coagulation thrombus in phlebothrombosis is less obvious. In the former disease, as mentioned previously, the clot formation is dependent on changes within the wall of the vessel, particularly in the intima. In the latter, thrombosis is dependent on an increased coagulability of the blood, which results from changes in the blood's constituents, because of trauma. Shafiroff and his co-workers[10] showed that 92 per cent of the patients with postoperative venous thrombosis and primary acute thrombophlebitis had hypercoagulability of their blood, and that the average acceleration of blood coagulation in these patients was four and one-half times that in normal subjects. Localization of the clot in the veins of the lower extremity is dependent on the slowing of the blood stream in that part of the body. It is my belief, as well as that of others, that as a result of tissue injury, and with few exceptions, whatever the cause of the injury, changes in the blood's constituents occur which favor blood clotting. This is undoubtedly a protective mechanism and is responsible for the lack of persistent hemorrhage in severe trauma. As a result of operative trauma, trauma during delivery, accidental trauma and the injury of tissue by the invasion of neoplastic disease or infection there is an increased clotting tendency. Because of its manifold causes it is essential that the possibility of venous thrombosis, particularly phlebothrombosis, be considered in all patients who have suffered a trauma. The greater the trauma, the greater the tendency toward thrombosis.

Although the increased clotting tendency is the underlying and predisposing factor in phlebothrombosis, the precipitating factor is circulatory stasis, and it is this factor which is responsible for the development of the thrombi in the veins of the calf muscles and on the plantar aspect of the foot rather than in the veins of the upper extremity. In addition to these two factors, increasing age (probably because of the associated cardiovascular disturbance) and alterations of the vascular system are particularly likely to be associated with venous thrombosis. The presence of cardiac disease is especially important in the production of venous thrombosis. Hunter and his associates[5] found at autopsy that thrombosis of the deep veins of the leg in middle aged and old persons who had been in bed for varying periods of time was as high as 52.7 per cent. The involvement was bilateral in 110 instances and unilateral in 75 instances. Allen[18] stated that 82.3 per cent of his patients with venous thrombosis were above the age of 40. Veal and Hussey[19] found that 70 per cent of their 84 cases of venous thrombosis were in patients over 40 years of age.

There is a definite relationship between venous thrombosis and the seasons. This has been repeatedly emphasized.[3b, c] Allen, Linton and Donaldson[21] observed 32.9 per cent of their cases in the winter, 21.9 per cent in the spring, 18.9 per cent in the summer and 20.3 per cent in the fall in a series of 332 cases. It is my belief that the increased incidence of venous thrombosis during the winter months is due to the vasospastic influence of the cold weather. This explains the difference between the incidence of venous thrombosis observed in the northern and in the southern clinics. My associates and I[3e] showed that the incidence of venous thrombosis in the northern clinics was almost double that in the southern clinics. The average incidence in the northern states was 0.74 per hundred thousand population as contrasted with 0.41 in the southern states.

Other predisposing factors in this disease are obesity, debility, changes in the hemopoietic system, such as anemia and polycythemia, and excessive smoking.

As mentioned previously, increased coagulability resulting from changes in the blood's constituents because of tissue injury is one of the most important factors in the production of venous clotting, particularly phlebothrombosis. These changes in the blood are manifold, and the exact role played by each is not known, but probably all combine to exert a definite effect on the clotting mechanism.

In addition to the predisposing factors which favor blood clotting, the precipitating factors as mentioned previously are those which cause circulatory stasis. Any condition which produces a slowing of the blood stream is likely to result in the production of a coagulation thrombus in a person with an increased clotting tendency as a result of tissue damage. McCartney[1] pointed out that venous thrombosis occurred five to six times more frequently in cases which showed chronic passive congestion in the liver than in cases in which the liver was normal. The movement of blood in the venous system is dependent on a number of factors, such as the vis a tergo through the capillary bed, which varies according to the degree of vasodilatation or vasoconstriction and depends on cardiac function. Naide[28] expressed the opinion that patients with a high grade vascular tone are particularly likely to have venous thrombosis develop because of diminished blood flow. In a series of 17 cases, 16 patients had a high grade vascular tone. Smoking would be particularly detrimental to such patients. Another factor in favoring the movement of blood in the venous system is the negative pressure within the thorax, facilitating the flow of blood from the distal parts of the body. The third, and probably the most important, factor in the movement of blood in the venous system is the active contraction of the skeletal muscles. Prolonged rest in bed is an important factor in producing circulatory stasis, unless measures are instituted to obviate it. Although the patient who is in bed frequently moves his hands and arms, reaches to the bedside table, places his hands on his head or moves them to his face, he is likely, unless otherwise instructed, to keep his lower extremities perfectly motionless. This lack of muscular contraction is a great factor in producing retardation of the blood in the lower extremities. If the patient has been subjected to an abdominal operation or has had an injury of the abdominal cavity, he is less likely to breathe deeply because of the pain resulting from deep inspiration. This favors circulatory stasis, and as a result of a trauma, particularly of the abdomen, there is the likelihood of diminished circulation in the lower extremities because of vasospasm. If, in addition to these factors, there is increased intra-abdominal tension because of abdominal distention and the use of tight bandages, stasis within the veins of the lower extremities is greatly increased. The position which the patient assumes in bed is of importance. If he is placed in a head up position or particularly in a Fowler's position with the knees flexed on the thigh and the upper part of the body elevated, stasis in the calf veins is favored not only by gravity but also by the kinking of the popliteal veins in the popliteal space.

SYMPTOMATOLOGY

As mentioned previously, the differentiation between phlebothrombosis and thrombophlebitis must be made not only from an etiologic standpoint but also from that of clinical manifestations. In most cases of thrombophlebitis, the clinical picture is definite and well defined. The patient usually complains of pain in the involved extremity, there is usually a pyrexia, and with few exceptions there is swelling of the extremity. Color changes in the extremity are of significance. In cases with deep vein involvement (the type which is more common) there is a characteristic whiteness of the extremity, as suggested by the descriptive term "phlegmasia alba dolens." The temperature of the skin of the involved extremity is cool, which is an obvious paradox in view of the increased surface temperature of the rest of the body.

In superficial vein involvement the skin overlying the affected vein is red and warm. The fever is due to the inflammatory process in the involved extremity; the pain is due to an ischemia and is relieved by vasodilatation. The whiteness of the extremity, concerning which there has been considerable controversy in the past, is unquestionably due also to vasospasm, and this too is relieved by vasodilatation. The edema in thrombophlebitis was previously thought to be caused by increased venous pressure which resulted from the obstruction within the involved vein. The fact that a large vein such as the femoral, iliac or even vena cava can be ligated with the production of only transitory edema is certainly evidence against the hypothesis that the edema is due to obstruction of the vein. My associates and I[29] have previously shown that the edema is due to the ischemia resulting from arteriolar spasm and is promptly relieved by vasodilatation.

Although the patient with thrombophlebitis appears ill and is uncomfortable because of the pain, fever and swelling, the patient with phlebothrombosis is likely to have no symptoms whatever. In fact, I am convinced that the diagnosis must be made before any symptoms are manifest because usually the symptoms are the result of a complication, such as infarction or a beginning inflammatory process resulting from the retained thrombus. Although many of these patients complain of a sense of impending disaster (which should be considered of great significance in a patient who has had any tissue injury, because of the likelihood of an existing phlebothrombosis) they usually do not have fever. There may be an elevation of the pulse rate which is decidedly out of proportion to any elevation of temperature, because the latter, if present, is almost insignificant. An almost constant observation is an increased erythrocytic sedimentation rate. Because the patient with phlebothrombosis has few or no symptoms, the diagnosis must be made by careful routine examination of the lower extremities in all patients who have had any tissue damage. It is my rule routinely to palpate the calf muscles and the plantar aspect of the foot and to dorsiflex the foot forcefully (Homans' sign) in all patients who are in bed and who have had tissue injury. The detection of tenderness in the calf or on the plantar aspect of the foot, or the production of pain in the calf or popliteal space when the foot is forcefully dorsiflexed is indicative of phlebothrombosis. Although previously I thought that a suspected phlebothrombosis should be verified by phlebography, I now believe that phlebography is not necessary, and that immediate therapy should be instituted before the clot has a chance to become detached.

PROGNOSIS

The prognosis in thrombophlebitis and that in phlebothrombosis differs considerably in the untreated patient, although the prognosis need not be bad in either instance, if appropriate therapy is instituted early. The patient with thrombophlebitis, unless there is suppuration (in which event the thrombus may be liquefied with the detachment of small septic emboli) usually gets along well and does not succumb to the thrombotic process. The patient is likely to have postphlebitic symptoms which may last for many years. These consist of swelling, pain, possible ulceration and streptococcic infection in the involved extremity. The patient may be incapacitated for months, for years or for the rest of his life. On the other hand, the patient with phlebothrombosis is a potential fatality unless active measures are taken, because the thrombus is not firmly attached and can become detached on the slightest exertion. Although nonfatal infarction with a resulting pneumonitis can occur, the possibility of a massive pulmonary embolism resulting in sudden death is not only feasible but likely.

THERAPY

The initial treatment of venous thrombosis consists of prophylaxis. It is my belief that in most cases clotting within the venous system can be prevented if appropriate measures are instituted. Preoperatively, it is important that patients with cardiovascular disturbance should be treated to reestablish the cardiovascular function before a contemplated operative procedure is undertaken. This is particularly important in older persons and in patients with cardiovascular disease. I believe, too, that a patient who is to undergo an operative procedure should refrain from smoking for a period of from ten to fourteen days preoperatively because of the vasoconstrictor effect of smoking. Duryee[30] has emphasized the importance of this. Naide[28] showed that patients with increased vascular tone have a greater tendency to venous thrombosis. In order to increase the rate of blood flow through the deep veins it has been my practice, for many years, to apply compression bandages to the extremities in patients 40 years of age or older who are subjected to an operative procedure. No. 8 Ace bandages are applied to both lower extremities from the toes to the groin before the patient leaves the operating room. This is done not only in patients who have undergone an operation, but also in nonsurgical patients in whom there is destruction of tissue as a result of infection, neoplastic disease or trauma. The compression of the superficial veins by means of bandages increases the flow of blood through the deep veins and overcomes circulatory stasis. This is particularly advisable in the patient who has varicosities, because of the greater likelihood of the stasis of blood in the dilatated superficial veins.

Since obesity is a factor in predisposing to venous thrombosis, reduction of weight in the elective surgical case is of importance before the operative procedure is attempted. Also, the correction of any blood dyscrasia, such as anemia or polycythemia, is extremely desirable as a prophylactic measure.

Since the increased coagulability of blood is dependent on tissue injury, it is imperative during an operative procedure to avoid as much trauma as possible. The use of sharp dissection, the avoidance of mass ligation and the use of fine nonabsorbable suture material (particularly cotton, because it produces a minimal amount of wound reaction) decrease the tendency toward clotting. The prevention of circulatory collapse during the operation and the immediate postoperative period by the administration of fluids, and particularly by the reestablishment of blood volume, are of importance. Postoperatively, the avoidance of abdominal distention by means of the indwelling duodenal or double catheter along with the avoidance of tight abdominal bandages will decrease the pressure exerted on the abdominal veins which, in turn, will tend to obviate the stasis of blood in the lower extremity. A patient who has recently been operated on should be placed in the head down position immediately on return to his room, because in this position gravity favors the return of venous blood from the lower extremities. This position should be maintained until the patient has recovered sufficiently to contract actively the muscles of his leg and thigh. The head up position, particularly Fowler's position (the patient in the sitting position with the legs flexed on the thighs) must be avoided for the reasons which have already been given. As soon as the patient can do so, active muscular contraction of the calf muscles against a resistance is imperative. I insist on forceful ventroflexion of the foot against resistance many times during the day. In order to increase the return venous flow deep breathing is essential; by increasing the negative pressure within the thorax, the blood flow into the thoracic veins is favored.

Early ambulation of the patient is of importance in decreasing the incidence of venous thrombosis, but simply getting the patient out of bed is not sufficient to protect against venous clotting. In fact, many instances of so-called ambulation actually do more harm than good. Certainly, to allow a patient to sit in a chair with his legs dependent produces greater circulatory stasis in the veins of the lower extremity than that produced if he contracts his musculature actively against a resistance while lying in the horizontal position. If by ambulation it is meant that the patient walks, this will undoubtedly decrease the incidence of venous thrombosis.

Although theoretically the administration of anticoagulants to all patients who were operated on might be of value, I believe that their use is too dangerous to be invoked routinely. In the person who has had previous thromboses and who probably has a thrombosing tendency, heparin or Dicumarol (3,3'-methylene-bis-[4-hydroxycoumarin]) prophylactically might be used immediately after operation. In this way, the possibility of thrombosis could be avoided. In fact, it is my feeling that the use of anticoagulants should be limited largely to patients in this classification. Allen[21] used Dicumarol prophylactically in a series of 101 cases in patients between the ages of 40 and 65. In 3 patients venous thrombosis developed and in 6 there was some hemorrhage which may or may not have been due to the anticoagulant. De Takats[32] has warned that if anticoagulants are used in conjunction with sulfonamides great caution should be exercised, because sulfonamides increase the heparin sensitivity. Similar caution is necessary when anticoagulants are used with neostigmine—de Takats and Fowler[33] Reich and others[34] have also used anticoagulants prophylactically with good results.

ACTIVE THERAPY

The active treatment of venous thrombosis, once the thrombus has occurred, differs according to the type of thrombosis; and the urgency also varies according to the type. In thrombophlebitis in which, as has been mentioned, there is fever, pain and swelling of the extremity, the treatment consists of vasodilatation secured by procaine hydrochloride block of the regional sympathetic ganglions since the symptoms in thrombophlebitis are due to vasospasm. It has been shown both clinically and experimentally that although the lesion in thrombophlebitis is limited to one of the major veins, the symptoms are dependent on associated arteriolar spasm, and that by relieving the spasm, the symptoms quickly subside. The pain is relieved instantly, the temperature falls rapidly and the swelling subsides within a few days. There is a dramatic response to procaine hydrochloride block of the regional sympathetic ganglions in an ill patient who is extremely uncomfortable; the patient is not only relieved of his symptoms but is also spared such persistent manifestations as postphlebitic edema, pain, ulceration and recurrent streptococcic infection. My experience has shown that the relief of pain is complete and permanent in 90 per cent of the patients, whereas in 10 per cent a second block is necessary to give permanent relief. Sixty-five per cent of the patients treated with procaine hydrochloride anesthetization of the regional sympathetic ganglions were fever free within forty-eight hours after the institution of therapy, 24 per cent in three to five days and 7 per cent in six to eight days. In only 4 per cent did the pyrexia last longer than eight days. The edema completely subsided within four days or less in 56 per cent, in from five to eight days in 32 per cent, in from nine to ten days in 8 per cent, and in from eleven to twelve days in 3 per cent. Sixty-two per cent of the patients were discharged from the hospital as cured within four to eight days after the institution of therapy, 19 per cent left the hospital between the ninth and twelfth days, and only 10 per cent remained in the hospital after twelve days. Similar results have been reported by many.[36]

The technic of the sympathetic block of the lumbar ganglions has been described repeatedly.[37] The injection of the first, second, third, and fourth lumbar ganglions, using 5 cc. of 1 per cent procaine hydrochloride into the region of each ganglion gives a satisfactory result. The injection should be performed every twenty-four hours as long as the patient has fever, because fever is an indication of the persistence of the inflammatory process. Although the pharmacologic effect of the drug persists much less than twenty-four hours, it is a well known fact that the physiologic effect of the injection of procaine hydrochloride into the sympathetic nerves lasts considerably longer than the pharmacologic effect.

In all uncomplicated cases of thrombophlebitis or phlegmasia alba dolens, conservative therapy is sufficient and, as exemplified by the results previously given, these patients are well within a short period of time. In the relatively rare case of suppurative thrombophlebitis, which is usually associated with a pelvic inflammatory disease resulting from criminal abortion in which there is liquefaction of the clot with the production of septic emboli, active radical therapy is imperative. Unless the involved vessel proximal to the site of involvement is ligated, septic infarction will continue, resulting in a fatality because of an overwhelming sepsis. In the past there has been considerable controversy among gynecologists concerning the advisability of venous ligation in these instances. The mortality rate has been extremely high because of their ultraconservatism. Miller[40] in 1917 collected 197 cases of puerperal pyemia treated by venous ligation with a gross mortality of 51.6 per cent. Unfortunately, at that time ligation was performed only as a last resort and usually when septicemia was already present. Since then the procedure has been used in many cases, although it has not become popular until recently. Dr. Conrad Collins[36b] of the gynecologic division has shown that the mortality rate in puerperal sepsis after criminal abortion can be greatly decreased by the early ligation of the vena cava and the two ovarian veins. If good results are to be obtained, the operation must be performed early, before sepsis has developed. Twenty-two patients with suppurative pelvic thrombophlebitis have been operated on by the gynecologic staff at Tulane University under the direction of Collins. Of these 22, 20 survived the procedure. One of the 2 fatalities was moribund when operated on and did not survive the operation. The other was admitted to the hospital late in the course of her disease and at the time of operation had extensive pulmonary suppuration. She succumbed six days later to suppurative disease of the lungs. These statistics demonstrate the advantage of radical therapy in suppurative thrombophlebitis and show that the previously accepted extremely poor prognosis in these cases is no longer necessary. Although there is some difference of opinion concerning the method of approach in ligating the pelvic veins in suppurative thrombophlebitis, I am convinced from my experience that transperitoneal ligation of the vena cava just above the bifurcation, together with ligation of the two ovarians, is the preferable method of approach.

With the exception of a suppurative process, the treatment of thrombophlebitis is that of conservatism. On the other hand, the treatment of phlebothrombosis in which the thrombus is not intimately attached to the vein wall and can be readily detached on the slightest exertion, is radical operative therapy in order to prevent the detached thrombus from being carried in the systemic venous system into the heart of the lungs. Although there are many (Barker[40a] and others[41] who believe that all forms of venous thrombosis can be treated by means of anticoagulants, it is my firm conviction that the use of anticoagulants alone in phlebothrombosis is hazardous, because, although the administration of anticoagulants will prevent the formation of additional thrombi, it will certainly not prevent the detachment of those thrombi which are already present. I cannot agree with Barker and his associates[40a] that when a thrombus is diagnosed clinically there is no danger that it may become detached and an embolus may form. As I mentioned before in discussing the symptomatology in phlebothrombosis, I believe that a coagulation thrombus can be detected by careful physical examination. Of course, if one waits until the clot becomes detached and produces pulmonary infarction or if the patient is fortunate enough that the thrombus

does not become detached until sufficient inflammatory reaction is formed in the vein to bring on a superimposed phlebitis, the diagnosis can be made without the careful examination. The observation of Hunter and his associates[5] that in 92 per cent of 209 autopsies in which thrombosis of the leg veins was found there was no evidence of phlebitis, is demonstrable proof that a bland thrombus can occur; and since it is not associated with evidence of inflammatory change, it is not fixed to the vein wall. I have repeatedly seen patients who have been treated with anticoagulants over varying periods of time, one for as long as five weeks, in whom there continued to be discharges of emboli which, fortunately, in most instances were not fatal. As mentioned previously, although the administration of anticoagulants will prevent the formation of new thrombi, it will in no way prevent the detachment of those thrombi which are already in existence; a false sense of security in the belief that everything possible is being done by the administration of anticoagulants is likely to lull one into a belief that the patient is in no danger.

Because the thrombus in phlebothrombosis is only loosely attached to the vein wall and can be detached by any slight exertion, it is my belief that immediate surgical intervention should be undertaken as soon as the diagnosis of phlebothrombosis is made. In fact, this condition takes precedence, as far as urgency is concerned, over any other case on the service except that of massive hemorrhage. I have known 2 instances in which a diagnosis of phlebothrombosis was made, but in which the operation was delayed until morning at the time of the regular surgical schedule. In both instances a fatal embolism occurred during the night, before the contemplated procedure was performed. Had the operation been performed at the time the diagnosis was made, these fatalities could have been averted.

Because the administration of anticoagulants will not prevent the detachment of clots (in fact, I know of nothing that will prevent the detachment of the clot), it is my belief that either ligation of the vein above the thrombus or opening the vein and aspirating the thrombus proximal to the opening with ligation below that site is imperative. This should be done bilaterally, because there is bilateral involvement in such a high percentage of the cases. Arthur Allen[21] and his associates at the Massachusetts General Hospital have had the greatest amount of experience with curative and prophylactic ligation for venous thrombosis. In a recent publication he stated that from 1937 to Oct. 1, 1945 1,468 veins were ligated in 816 patients. In this series bilateral ligation has become the method of choice. From 1937 to 1942, 280 veins were ligated in 202 patients; in 39 per cent the venous interruption was bilateral. In 1943, 299 ligations were performed in 165 patients, with 81 per cent bilateral; in 1944, there were 554 ligations in 280 patients, with 97 per cent bilateral, and in 1945, in 169 patients, 335 ligations were performed, of which 98.2 per cent were bilateral. The indications for ligation in the entire group were as follows: signs and symptoms of venous thrombosis in the leg veins, 47.37 per cent; signs of pulmonary infarction, 34.4 per cent, and prophylactic ligation in older persons likely to develop thrombosis, 18.3 per cent. The incidence of prophylactic ligation has increased from 9.2 per cent in 1943 to 25.7 per cent in 1944 and to 36.7 per cent in 1945. Whereas I agree heartily with the Boston group that venous ligation is imperative in phlebothrombosis I do not believe that ligation is necessary in thrombophlebitis except in the rare case of suppurative thrombophlebitis. The patient with nonsuppurative thrombophlebitis can be treated satisfactorily and expeditiously by vasodilation, and ligation in an instance in which the clot is firmly attached is unnecessary. However, to deny a patient with phlebothrombosis the advantage of the thrombectomy or ligation is hazardous because of the likelihood that detachment of the thrombus will produce nonfatal infarction or fatal embolism. Whereas femoral vein interruption is generally a fairly innocuous procedure, it probably should not be performed unless it is absolutely necessary.

The treatment of phlebothrombosis consists of exposure of the femoral vein in the upper end of Hunter's canal. This should be done under local anesthesia. The vein is exposed for approximately 6 cm. below the deep femoral and an incision made in the vein beneath the opening of the deep femoral. If there is free bleeding from the vein proximally, the superficial femoral distal to the profunda is ligated. If there is no free bleeding, a glass cannula is inserted proximally, with the maintenance of a mild suction as the cannula is introduced. In this way, the thrombus which extends proximally into the common femoral and possibly into the iliacs is aspirated. Aspiration is continued until there is free bleeding from the opening in the vein. Subsequent to this, the vein is ligated just above and below the opening. In most instances the involvement is limited to the femoral below the profunda. If, however, there is involvement of the profunda as well as the superficial femoral I believe that both the femoral and the profunda should be ligated. Homans[43] and Fine and Farr[44] have preferred ligation of the iliac to that of the femoral vein because they considered that there is less subsequent edema. Ingraham,[45] because of observations made on autopsy material, expressed his belief that femoral ligation is not sufficient in most cases, and little can be accomplished by it.

SUMMARY AND CONCLUSIONS

Venous thrombosis is a serious complication in both medical and surgical patients.

From the etiologic, pathologic, symptomatologic, prognostic and therapeutic point of view, it is necessary to differentiate between two types of venous thrombosis —thrombophlebitis and phlebothrombosis. Thrombophlebitic organic changes are found in the vessel wall as the result of perivenous lymphangitis produced by bacteria, toxins or an allergy. The thrombus which is the result of changes in the endothelium is firmly fixed to the vein wall. In phlebothrombosis the clot is the result of two major causes; a predisposing one which consists of increased blood coagulability as the result of tissue injury, and a precipitating one which is circulatory stasis. The thrombus is not firmly attached to the vein wall and can be detached easily.

The patient with thrombophlebitis has many manifestations, such as fever, pain, swelling and color changes in the extremity, whereas the patient with phlebothrombosis has few or no symptoms. The prognosis in thrombophlebitis as regards life is good; but unless adequate therapy is instituted postphlebitic sequelae such as edema, pain, ulceration and streptococcic infection are likely. On the other hand, the patient with phlebothrombosis, although apparently not ill, is a potential fatality. The treatment of uncomplicated thrombophlebitis is conservative and consists of vasodilatation accomplished by anesthetizing the regional sympathetic ganglions. Only in rare cases of suppurative thrombophlebitis is radical therapy necessary; this consists of venous ligation proximal to the site of suppurative thrombophlebitis.

Phlebothrombosis, because of the great likelihood that the clot will become detached and produce pulmonary infarction or massive occlusion of the pulmonary artery which will cause sudden death, should be treated without delay by means of venous ligation or thrombectomy. Anticoagulant therapy may be used prophylactically in persons known to have a thrombosing tendency; however, in the treatment of phlebothrombosis it will prevent the formation of additional thrombi but will not prevent the detachment of the thrombus which already exists.

EFFECT OF SEASON AND DUST CONTROL ON COCCIDIOIDOMYCOSIS

CHARLES E. SMITH, M.D.
RODNEY R. BEARD, M.D.
San Francisco
MAJOR H. G. ROSENBERGER
and
MAJOR E. G. WHITING
Medical Corps, Army of the United States

A complete description of the activities of the Commission on Epidemiological Survey of the Board for the Investigation of Epidemic Diseases, Preventive Medicine Service, will be presented in the Surgeon General's History of World War II. It may be mentioned here that a general consultative service was provided, together with standardized coccidioidin and facilities for serologic tests and Coccidioides identification. In conjunction with the Army Air Forces, a detailed epidemiologic investigation was carried out in four army air fields in the San Joaquin Valley, California (fig. 1). These investigations began in July 1941 at Minter and Gardner fields in Kern County, in February 1942 at Merced Army Air Field in Merced County and in March 1942 at Lemoore Army Air Field in Kings County. They continued until three of the fields closed, Gardner in March 1945, Lemoore in October 1945 and Minter in February 1946. On July 1, 1945, when Merced was transferred from the Training Command, the Merced study terminated because it had been shown that coccidioidomycosis was no problem there Actually, Merced served as an unexpected "control."

The intensive epidemiologic investigations were based on coccidioidin testing permanent personnel and at first annually, later semiannually, retesting the negative persons. When the study began, it was not known whether the coccidioidin reactors were also immune, but it was soon apparent that those who reacted did not undergo clinical infections. This immunity was seen both in those who were infected while on the fields and in those who were found to be positive on arrival at the fields. The permanence of immunity will be discussed in a subsequent paper. Likewise, the relatively long duration of coccidioidin sensitivity, comparable to that of tuberculin, will be presented subsequently. When the personnel previously negative were retested, it also became evident that the proportion of completely inapparent or asymptomatic coccidioidal infections was larger than that of clinically recognizable disease.

At approximately monthly intervals permanent personnel who arrived subsequent to the previous visit were coccidioidin tested. Freshly[1] diluted 1 : 100 lot 9 coccidioidin was used throughout the study as a 0.1 millimeter intradermal test. While our other coccidioidins have been standardized against this lot 9, it was felt that using one lot would avoid any question of difference of antigen at the time of the retest. Except for brief periods[2] and at the retest, one person gave the tests and interpreted the results. At the retests, sometimes another of the investigators would test or interpret. However, the permanent tester was working alongside, and the same technics and interpretations were employed. If there was a question, the opinion of the permanent tester was obtained.

Records were kept of all those tested. If clinical coccidioidomycosis occurred, notation was made. At the retest, all who previously failed to react, except those who were known to have had a clinical coccidioidal illness, again were tested. The newly revealed reactors ("change overs") were interrogated regarding illnesses, additional epidemiologic information was obtained, blood for erythrocyte sedimentation rates and coccidioidal serology was drawn and, if possible, pulmonary roentgenograms were taken. The army form 52 A infirmary records and the hospital histories were also checked for suspicious illnesses. Eliminating those originally tested but no longer present at the retest, we grouped the retested persons into the uninfected

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946

From the Commission on [illegible] the Investigation of Epidemic Diseases [illegible] Office of the Surgeon General The spec [illegible] have been conducted in the Department [illegible] University School of Medicine The first five months of the study were supported by a grant from the Rosenberg Foundation This has been a collaborative study Dr Francis G. Blake, chairman of the commission and president of the board, and Brig Gen S Bayne Jones, deputy chief of preventive medicine service, provided invaluable aid and counsel In the Army Air Forces Brig Gen Charles R Glenn while surgeon of the West Coast Training Center and the Training Command and ultimately as deputy air surgeon initiated and maintained Air Force cooperation This was carried through by the surgeons of the Flying Training Command, Col Otis B Schreuder and Col Michael G Healy, and the deputy surgeon, Col Bloyce H Britton, by Col Russel V Lee, chief of professional services at Santa Ana army air base, and by Lt Col Norman Nixon, coccidioidomycosis control office of the Western Flying Training Command, by surgeons of the Fourth Air Force, Col Fabian Pratt and Col. J. R Copenhaver, and the executive officer, Lt Col P M Pederson,

(Footnote continued in next column)

and by the surgeons at the respective fields. Minter, Col John Roberts, Col A L Jennings, Lt. Col E. C Donohoe, Lt. Col Benjamin Siebenthal, Lt Col Roger E Weismann, Major Edward J Hall and Major Maurice Foley, Gardner, Col Robert R. Estill, Col Albert Phillips and Major Robert G McCurdy, Lemoore, Col Edmund H Padden, Col D. D. Fodorovic Lt Col Harris D Joe and Lt Col M S Wessell, and Merced, Col M L Prescott, Col Neill Johnson and Lt. Col A. F. Dorner. The coccidioidomycosis control officers and chiefs of medicine contributed greatly to the study Besides Major Homer G. Rosenberger, these Minter collaborators included Lt Col Russell W. Mapes, Lt Col. Ian B Hamilton, Major Maurice P. Foley and besides Capt E Gale Whiting at Lemoore, Lt. Col J Murray Kinsman and Lt Col. Richard D. Evans These collaborators at Gardner Field were Majors David H. Thurman and Clarence J. Keefe and at Merced, Majors Harvey A. Woods and Harry E Thompson, Capt David C Whitehead The roster of collaborating ward officers is too large to enumerate Special mention should be given the hospital administrative officers who facilitated our work, particularly Chief Warrant Officer Melburn Biddulph at Minter. Key enlisted personnel who arranged for the scheduling and checking at tests included M/Sgt Howard Sehlin at Minter, Pfc. (later Lieutenant) Wilbert M. Fitzpatrick and Sgt C. O. Castledine at Gardner and Sgt. Robert A. Kunde at Merced Many others assisted, including the various commandants, executive officers and Air Force commissioned and noncommissioned officer personnel The post engineers, Major Daniel Eckerman of Minter, Capt Clarence Church of Gardner and Capt Robert H Johnson of Lemoore, worked closely with us, as did Mr. H. J. Cremer and Major Howard B Sprague, Army Air Force liaison officer, at the Ninth Service Command United States Army Engineers

[1] Studies have shown that if it is kept refrigerated and uncontaminated, coccidioidin in a 1 : 100 dilution retains its full potency over two years, at room temperature its potency is retained for well over six months

[2] During the five months from July to December 1941 Dr. E. E. Baker served as an associate in the testing at Minter and Gardner Fields, as did Dr William Kirby during the period from February to April 1942 at Merced Field

(still negative to coccidioidin) and the infected. The infected group included completely inapparent infections and clinically recognizable disease. The latter group included those patients whose histories showed either that their infections were not diagnosed when they were seen by the medical officers (missed cases) or that they did not report for medical care but "toughed it out" (atypical cases). To these undiagnosed cases in which the histories established that the patient had undergone clinical illness which could be allocated to a specific month of onset were added those clinically diagnosed cases still present at the retest.

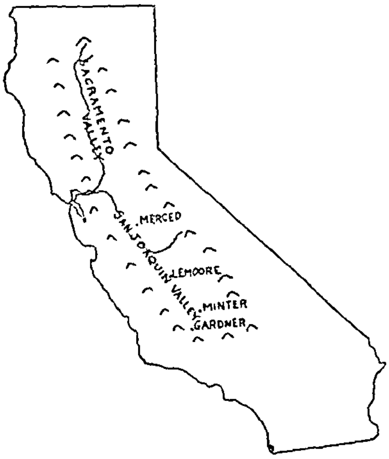

Fig. 1.—Location of the four San Joaquin Valley, California army air fields which were the basis of the coccidioidomycosis study.

The first inquiry which invariably arises concerning coccidioidomycosis is the rate at which infection is acquired. The extremely rapid turnover of personnel made this calculation rather difficult. Of 1,200 nonreactors tested at Minter Field in July 1941, only 221 were present at retest one year later. We found that 52 had undergone infection, a rate of 24 per cent. Actually, this checked closely with 25.1 per cent calculated by the method to be described later. However, there were other years and other fields when the changes were even more drastic and additional calculations became necessary. Moreover, these calculations were imperative in estimating seasonal incidence.

The infection rates for the retested men were calculated as follows (table 1): The "inapparent infections" (column 3) were allocated to the months (column 1) according to the monthly percentage distribution of all clinically recognizable disease occurring in the field regardless of whether the former patients were still on the field (column 2). It was not possible to allocate "inapparent infections" solely on the distribution of those still present who had clinically recognized disease since those still present were frequently so few that the fluctuation would have been like a tidal wave. The estimated "inapparent infections" (column 3) and the clinically recognizable infections present at the retest (column 4) were added to give the total number of infections per month (column 5). Newly tested negatives (column 6) were added to the residual negatives of the previous month (column 7, comprising column 8 minus column 5) to give the total number of those still negative and susceptible (column 8). The infection rate per 100 men (column 9) was calculated by dividing all infections (column 5) by total susceptibles (column 8). The monthly rates were then added to give the annual rate. It is to be observed that at Merced, where no clinically diagnosed infections were ever found to have been acquired on the field, it was impossible to calculate monthly infection rates. The annual infection rates were estimated by taking the number of coccidioidin negatives at the midpoint between the retests.

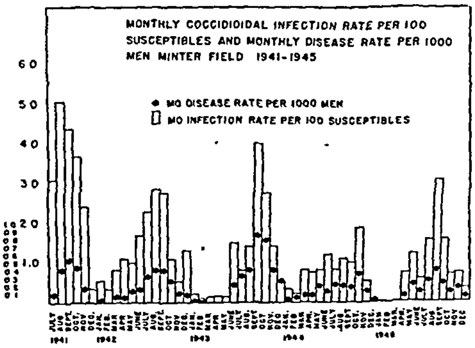

Fig. 2.—Monthly coccidioidal infection rate per 100 susceptible persons and monthly disease rate per 1,000 men at Minter Field, 1941 to 1945.

In table 2 are presented the monthly infection rates per 100 susceptible persons at Minter, Gardner and Lemoore together with the monthly precipitation in inches at the U. S. Department of Commerce Weather Station, Kern County Air Port, Bakersfield, Calif. For comparison the Minter Field monthly disease rate per 1,000 men field strength (total Army population on the field) is also given. The latter differs from the War Department records in that casuals were omitted and cases were allocated to month of onset rather than month when diagnosed. Figure 2 depicts the Minter Field infection rate per 100 susceptible persons and this monthly disease or case rate based on field strength. One notes the extremely poor monthly association. Indeed, the third coccidioidal season produced monthly disease rates higher than did the first, although calculated infection rates were significantly less. Figure 3 compares the monthly infection rates at Minter, Gardner and Lemoore, while figure 4 compares the monthly incidence at Minter Field with the monthly rainfall.

Table 1.—*Example of Method of Calculating Monthly Coccidioidal Infection Rates, Minter Field, 1941 to 1942*

Inapparent Infections Distributed According to Monthly Incidence of Clinically Recognized Cases July 1941 to June 1942

Month	% Distribution of All Clinically Recognizable Cases*	Inapparent Infections	Clinically Recognizable Infections Present at Retest	All Infections	New Negatives	Previous Negatives Still Negative (8)—(5) of Previous Month	Total Susceptibles; (6)+(7)	Infection Rate per 100; (5)÷(8)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
July	4.8	5	2	7	221	0	221	3.17
August	10.7	12	7	19	157	214	371	5.12
September	16.7	19	5	24	186	352	538	4.46
October	16.7	19	7	26	206	514	720	3.75
November	11.8	13	6	19	78	694	772	2.46
December	1.2	1	2	3	0	753	753	0.40
January	3.6	4	2	6	321	750	1,071	0.56
February	2.4	3	1	4	0	1,065	1,065	0.38

June	11.9	13	15	28	206	1,427	1,633	1.71
Total	100.0	113	65	178	1,783			25.10

* There were 84 clinically recognizable cases of coccidioidal infection.

In table 2 the annual coccidioidal rates are presented for Minter, Gardner, Lemoore and Merced. Again one observes the inapplicability of the usual disease or case rate based on field strength. If one merely takes the average field strength for the year as a whole as the basis of computation, the results are even farther out of line. One fact is outstanding. Minter and Gardner, in the southern part of the San Joaquin Valley, have exceedingly high rates. In their first year with dust uncontrolled, 1 out of every 4 or 5 susceptible persons was infected. Lemoore, 50 miles to the north, had half or less while Merced, another 75 miles north, had a negligible amount. Many of the "inapparent infections" detected at Merced were in men who had traveled into the southern part of the San Joaquin Valley. The Merced 1944-1945 calculations were complicated by the fact that at the time of the retest, Feb. 6, 1945, a considerable portion of the field personnel had migrated to Gila Bend, Ariz., because the land fogs in the San Joaquin Valley interfered with the training schedule. In the 728 previously negative persons who did not go to Gila Bend, the infection rate was only 0.5 per cent (essentially the same as in the previous two years). However, of 204 susceptible persons who went to Gila Bend January 6 to February 19, 4.8 per cent were found to be infected. Certainly the pattern of increased coccidioidal endemicity in the southern part of the San Joaquin Valley with a decrease as one proceeds northward is remarkably clear together with the implication of a high rate of incidence in Arizona.

The outstanding importance of dust in coccidioidomycosis is also apparent. Dust has been repeatedly [3] commented on as constituting the vehicle of "natural" infection. Coccidioidal chlamydospores are readily wafted in the air. The coccidioidal sporangia ("spherules") are infective when they are introduced into an animal's tissues.[4] However, they are much larger and do not constitute part of the infection chain unless, as Emmons hypothecates,[5] infected rodents die and their bodies furnish a medium in which the myceliums develop and infect the soil. Cattle,[6] sheep [6b] and dogs [7] as well as rodents and man are infected from the dust. When susceptible human beings stir up dust in highly infected areas, veritable epidemics occur.[3c, d] The seasonal characteristics of coccidioidal erythema nodosum ("valley fever") have been noted,[3b] but table 2 and figure 4 show this association with even greater clarity.

Table 2.—*Annual Coccidioidal Rates in San Joaquin Valley Army Air Fields and Precipitation at Bakersfield, Calif., 1941 to 1945*

Year	Precipitation Previous Rainy Season	Minter (7/1 to 6/30) Disease Rate per 1,000 Men (Field Strength)	Minter (7/1 to 6/30) Infection Rate per 100 Susceptibles	Gardner (7/1 to 6/30) Infection Rate per 100 Susceptibles	Lemoore (3/1 to 2/28) Infection Rate per 100 Susceptibles	Merced (2/1 to 1/31) Infection Rate per 100 Susceptibles
1941-42	10 96	2.16	25 10	20 99

* Gardner, July to November

† Merced affected by Arizona exposures. See text.

‡ Minter, July to December

§ Lemoore, March to September.

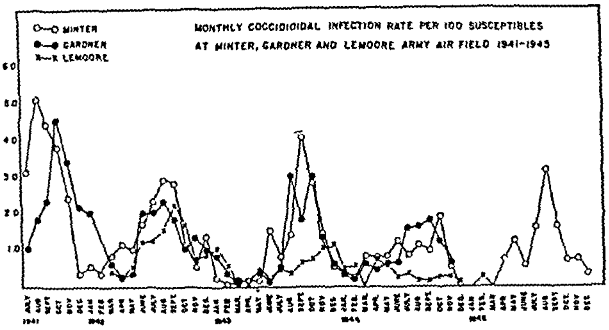

Fig. 3—Monthly coccidioidal infection rate per 100 susceptible persons at Minter, Gardner and Lemoore army air fields, 1941 to 1945.

Recalling that the incubation period of coccidioidal infection is eight to twenty-one and possibly thirty days,[3b, c] one observes that the effect of rainfall is reflected not only in the month when the rain occurs but also in the succeeding month. The incidence is maximal in the dry summer and autumn, minimal during the winter and spring. The only exception in the data presented is in the Lemoore 1944 season (fig. 3). However, in June 1944 Lemoore changed from an active dust-raising training field to a much more sedentary processing center.

In the fall of 1941 when Minter and Gardner were being built there were extensive scarred surfaces and the dust billowed in clouds. That season of maximal dust provided the highest coccidioidal rates of the study (tables 2 and 3, figs. 2, 3 and 4). In the month of August 1941 over 5 per cent of the susceptible Minter Field personnel were infected.

The following year lawns were planted, roads were paved, air strips both at the main and auxiliary fields were hard-surfaced and the incidence of coccidioidal infections was cut in half. It may be noted (table 2) that the winter preceding the 1941 coccidioidal season had twice the rainfall of the succeeding winter, while the winter preceding the 1943-1944 season was another rainy one (for the San Joaquin Valley). There was an increase in coccidioidal incidence at both Minter and Gardner, suggesting that a wet winter season may aid in the multiplication of the fungus in nature, by whatever means this is accomplished. The immediate beneficial effect of rain in keeping the chlamydospores from blowing about in the air is obvious. Admittedly, the effect of heavy winter rainfall in providing abundant chlamydospores for inhalation in the succeeding summer is hypothetic.

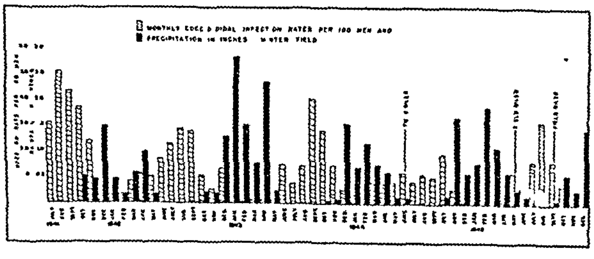

Fig. 4—Monthly coccidioidal infection rate per 100 susceptible persons and precipitation in inches at Minter Field, 1941 to 1945.

The pattern of maximal incidence in the first year of operation of the fields was seen at Lemoore. As table 2 indicates, the second year of operation at Lemoore provided an infection rate just one half that of the first season despite the fact that this was a heavy coccidioidal season, as indicated by an increase over the previous year both at Minter and at Gardner. The improvements in local dust control more than offset more favorable conditions for Coccidioides.

* Precipitation data from U S Department of Commerce Weather Station, Kern County Air Port, Bakersfield, Calif

After the relatively severe coccidioidal season of 1943-1944 at Minter and Gardner fields, concerted action was taken on other phases of dust control. The Board for the Investigation of Epidemic Diseases requested us to direct our attention to the problem. It was also receiving urgent study by the Air Surgeon's Office. At the fields the commandants, post surgeons, post engineers and Coccidioidomycosis Control Officers were working on the problem. With the encouragement and backing of Washington and the Ninth Service Command and Training Command, they took energetic steps.

It was recognized that in highly endemic areas coccidioidomycosis is bound to occur even if local dust control is reasonably effective. Dust blows in from areas surrounding an installation. Personnel do not stay on a post continuously. However, surfacing the roads, grassing the grounds and compelling personnel to use surfaced roads and walks rather than permitting them to wear away grassed areas and lawns greatly reduce the amount of local dust. The Pacific Division of Ninth Service Command U. S. A. Engineers prepared an excellent treatise on agronomy in passive protection from dust.

Two additional steps were taken. More swimming pools were constructed so that, as much as was possible, aquatics were substituted for other forms of exercise. Indeed, the principal areas left without turf were fields used for calisthenics, baseball, volley ball and other forms of physical training. Some of these areas had an asphalt (blacktop) surface, but asphalt is not only expensive but also hard on feet during the extremely hot weather.. The use of crushed rock and gravel was out of the question because of injuries which would ensue. These activities could not be abandoned completely, while control of dust in those areas seemed especially important since with exercise there is deeper breathing and an increase in the amount of air actually inspired. Therefore, an attempt was made to control the dust by the use of oil. Crude oil forms a crust which breaks up in lumps. Moreover, unless it is highly refined oil stains skin and clothing and is apt to be irritating. However, a number of highly refined oils are available. Such oil penetrates the upper inch of soil, impregnating the particles of dirt. Then even if the treated soil breaks up into dust and is scuffed, the oiled particles fall back to the ground instead of being blown about in clouds.

Accordingly, in May 1944, both Gardner and Minter fields embarked on the use of oil for athletic areas. Gardner's first attempt in early May was unsuccessful. Initially it was thought the failure was due to a preliminary disking. While it is true that the more heavily the soil is packed the better, the major fault proved to be in the character of the soil. Gardner Field was built on the fine silt of an old lake bottom. Even with a second, heavier application in June, the oil crust broke through and unoiled dust was exposed.

The soil at Minter Field, heavier and with more clay, proved more suitable. Preliminary tests were run on volley ball courts to estimate oil dosage. It was observed that 1 quart of oil per square yard was optimal. The oil was applied in late May and early June. While the dust control was only moderately effective at Gardner Field for a few weeks after each oil application, at Minter Field it seemed reasonably satisfactory until October Fortunately, as it was wearing off, late October rains terminated the coccidioidal season.

The effect of the oiling is seen in table 3 and figures 3 and 4. It is to be recalled that oil was applied to Gardner Field in early May and again in late June 1944, while athletic areas at Minter were oiled in late May and early June 1944. Also, by October the effect of oiling had largely worn off at Minter. The low incidence at Minter may be partially attributed to the preceding dry winter; however, not only was the Minter rate the lowest in its experience but also, for the first time, the June through November rate was below that of Gardner. During that six month period the infection rate at Minter was 6.87 per 100 susceptible persons, while that at Gardner was 7.69. Although this difference is not spectacular, in 1943 the same six months provided a 12.22 infection rate at Minter compared with that of 10.14 at Gardner. In 1942 the rate was 11.52 at Minter and 10.68 at Gardner. During the five months July through November 1941, it was 18.98 at Minter and 13.40 at Gardner. During 1942 and again in 1943 the Minter rate exceeded the Gardner rate in four of those six months; in 1944 the Gardner rate exceeded Minter in four of the six months. Minter was below the Gardner rate only this one season when oiling succeeded at Minter and failed at Gardner.

Another item of evidence was available. In the six months of summer and autumn of 1943, the Minter Field medical detachment enlisted personnel suffered 15 coccidioidal infections. The number of susceptible persons was an even 100, so the infection rate was 15 per 100 men. Athletic fields were behind the station hospital, with the barracks of the enlisted men directly at the edge of the athletic areas. In the same period of 1944 only 2 infections were acquired. Forty-two of those persons originally negative at the beginning of the six months were still present at the retest. The infection rate calculates to 5 per 100 men. Admittedly, the numbers are small, but the trend coincides with the rest of the evidence.

The closing of Gardner Field eliminated subsequent comparison. However, the 1945 experience at Minter provided additional evidence. After a record-breaking initial three months without any infections, cases appeared in April and by mid-May were increasing rapidly. The post engineer acceded to the pressure and began the application of oil on May 20. He had been reluctant because he feared late rains and knew that rains would render the oil less permanent. His fears were justified, for only a week after the oil was applied it began to rain and rained a total of 0.33 inch. The combination of oil and rain did drop the coccidioidomycosis, but because the rain had interfered with the durability of the oiling, by August the areas were extremely dusty. August provided a rate nearly twice that of any month in 1944 and exceeded only once since 1941. Oil was reapplied the first week in September with immediate cessation of coccidioidomycosis.

The most dramatic tribute to the efficacy of the Minter dust control was a comparison with members of two camps of agricultural workers in the same region. Only clinically diagnosed, hospitalized cases could be compared, but with the availability of diagnostic facilities at Minter Field it is conservative to consider that the clinical diagnoses were made with as great care and our Army personnel were hospitalized in no greater proportion than were the agricultural workers. Within a two month and ten day period extending from June into August, 22 Minter Field personnel were hospitalized for coccidioidomycosis compared with 150 agricultural workers. The field strength at Minter was approximately 3,400, while there were only 1,500 agricultural workers.

Working with different data, Major Howard B. Sprague has assembled decidedly convincing evidence of the beneficial effect of dust control on coccidioidal incidence.[8] One of his most telling items was a comparison of the incidence of coccidioidomycosis at Davis-Monthan Field and at Marana Army Air Base. Both fields are located near Tucson, Ariz., and have comparable soil and climate. Until 1944 the incidence of coccidioidomycosis was similar. In that year dust continued unabated at Marana and coccidioidomycosis soared in the summer and autumn. However, strict dust control was inaugurated at Davis-Monthan early in 1944. These measures were successful and were followed by almost complete elimination of hospital cases of coccidioidomycosis during the summer and autumn.

COMMENT

The seasonal infection rate of coccidioidomycosis again evinces that dust is the mechanism by which the fungus is transported. Even where the coccidioidal infection rate is 5 to 10 per cent per year, it is easy to understand why most of the long-time inhabitants have been infected. It is doubtful if a community in such an area could profitably essay complete dust control in order to prevent coccidioidomycosis among its citizens. However, lawns, parks, paved roads and dust-free playgrounds are pleasant, especially in the hot regions where Coccidioides flourishes. Certainly, sanatoriums located in coccidioidal endemic areas to take advantage of the warm dry climate should have the benefit of dust control measures.

In the special conditions which prevail in army camps in coccidioidal areas, where large numbers of susceptible persons are being introduced and those infected are departing as fast as they are becoming immune, local dust control seems warranted. Whenever feasible, grassing should be used. The surfacing of roads and, to a limited degree, that of athletic areas is important. However, many athletic areas cannot be surfaced because of heat on the feet and the danger of injuries after falls. If turf cannot be maintained on the areas, the application of a highly refined oil may be tried. However, one should first examine the character of the soil. If the soil is a fine loose silt like that of Gardner Field, success is unlikely. If it is a heavy adobe type, the outlook is favorable. In any event, one should run preliminary tests to prove effectiveness, to decide on the product to be used and to fix the quantity to be applied. In addition, every effort should be made to develop an aquatic physical training program during the suitable hot months, which will correspond with the season of high coccidioidal exposure.

SUMMARY

The monthly and yearly rates of coccidioidal infection were calculated in susceptible (coccidioidin negative) personnel of four San Joaquin Valley army air fields. The results emphasized the geographic distribution of the endemic area and the importance of dust in infecting man with Coccidioides immitis. At the most northerly station the annual infection rate was only 0.5 per 100 susceptible persons compared with 20 to 25 at the two southerly fields when dust was uncontrolled. Maximal incidence occurred in the arid dusty summer and autumn, a single month providing 5 per cent of the infections. Grassing, paving roads and runways and ultimately the use of highly refined oil on athletic areas were important dust control measures. This control reduced infection rates from one half to two thirds.

ABSTRACT OF DISCUSSION

Dr. Russell V. Lee, San Francisco: Dr. Smith and his associates know more about coccidioidomycosis than any one else, and this work with the Army Air Forces and Ground Forces was a most remarkable piece of combined epidemiology and curative medicine. They surveyed every man in that important military area, important because most of the training fields for the Army Air Forces were located within the area where coccidioidomycosis is prevalent. Dr. Smith was of great help in outlining the problems which might be encountered, and one type threatened to be a considerable menace. It was shown in the paper that dust control could remarkably reduce the incidence of the disease in an area where, left alone, in a year or two the incidence of infection would increase remarkably, and after a number of years' residence in the area we were practically 100 per cent uninfected with coccidioidomycosis. While the mortality was very low, it was the principal cause of hospitalization in many of the Air Force hospitals in that southwest area, so that anything that can be done to reduce it under such circumstances should be done. The incidence under military conditions, particularly under air conditions, was very high. The airplane propeller picks up a lot of dust; soldiers around camps and marching in physical training kick up a lot of dust, and they have become infected at a terrific rate. There was a hospital at San Benito where about one fourth of the men of one detachment were hospitalized and thus saved from going back to this exceedingly dusty region right in the middle of the season of highest incidence. This has lessons for civilian application. This whole desert area has been outlined now largely by the work of Dr. Smith. He can draw a very accurate line around the endemic area of coccidioidomycosis. It is a much larger area than was ever dreamed of before, and when certain types of activities are going to be carried out in that area certain precautions will have to be adopted to protect against coccidioidomycosis. For instance, we had Negro troops in that area, and the Negro is many times more susceptible to coccidioidomycosis than the white man. Negroes should be kept out of that area and the dusty occupations there. It is definitely a hazard for them, judging by the army experience there. In due time there is going to come from Dr. Smith's work the most comprehensive, complete definition of the clinical features as well as the epidemiologic features of coccidioidomycosis. The knowledge of this disease is exactly 50 years old, but in the last five years the whole thing has crystallized. Papers and monographs undoubtedly will appear shortly as a result of this army experience, and this disease is going to be defined with a precision with which it has never been defined before.

Postwar Malaria.—In continental United States civilian malaria in the aggregate is at an all time low; there has been little perceptible change in the past five years. Available data show a marked decrease in malaria rates among continental military personnel since 1941, but in these figures is reflected the extensive control programs in military areas. The cyclic upswing predicted for the early forties by some malariologists has not occurred. In the past two decades reported malaria mortality and morbidity have dropped 85 per cent and 70 per cent respectively.—Hollis, Mark D.: Postwar Malaria Control in Continental United States, *J. Nat. Malaria Soc.*, June 1946.

RADIOACTIVE IODINE THERAPY

Effect on Functioning Metastases of Adenocarcinoma of the Thyroid

S. M. SEIDLIN, M.D.
L. D. MARINELLI, M.A.
and
ELEANOR OSHRY, B.S.
New York

Therapy of neoplastic disease usually consists of two phases: first, the treatment of the primary focus and, second, that of metastases. Specifically, in adenocarcinoma of the thyroid, the primary site together with its immediate extensions is conventionally treated by surgery, radiation or both. Distant metastases, if treated, are usually subjected to palliative external irradiation. This paper is a report of successful therapy of a case of metastatic adenocarcinoma of the thyroid treated by the principle of specific internal irradiation *with radioactive iodine.*

The earliest study of the uptake of radioactive iodine in 2 cases of carcinoma was reported by Hamilton and his associates[1] in 1940. In 1942 he described 2 more cases[2] in which tracer doses of radioactive iodine had been given to the patients prior to the removal of carcinomatous thyroids. Radioautographs of the excised glands showed no significant deposition of the radioactive iodine in malignant areas in any of these cases.

In April 1942, Keston, Ball, Frantz and Palmer[3] reported the first positive evidence of pickup of the radioactive iodine by a metastasis from a carcinoma of the thyroid. In a patient with multiple lesions, Geiger counter measurements showed appreciable uptake of radioactive iodine in only one of the metastases. Subsequently, from the autopsy, these authors[4] reported that "the bulk of the metastatic tissue was undifferentiated. The metastasis which showed consistent uptake of iodine was the only one which grossly resembled thyroid tissue and which, microscopically, showed chiefly well differentiated tumor."

Leiter, Seidlin, Marinelli and Baumann[5] in a report of 2 cases (1 of which is the subject of the present paper) of hyperthyroidism due to adenocarcinoma of the thyroid and to functioning metastases showed that the effect of thiouracil on the basal metabolic rate, plasma cholesterol, blood iodine and excretion of radioactive iodine in these patients was in every respect

From the Medical Division and Department of Medical Physics of the Montefiore Hospital and the Physics Department of the Memorial Hospital.

A preliminary report of this work was presented at the Clinical Research Meeting of the New York Academy of Medicine on May 16, 1945.

Aided by grants from the Dazian Foundation for Medical Research and from the Lederle Laboratories to Dr. S. M. Seidlin at Montefiore Hospital.

The cooperation of the staffs of the Massachusetts Institute of Technology and Washington University cyclotrons and of Dr. R. D. Evans made this work possible.

Dr. Louis Leiter, Chief of the Medical Division of Montefiore Hospital, gave valuable assistance throughout this work, as did Dr. David Marine and Dr. S. H. Rosen in the field of thyroid pathology and Dr. E. J. Baumann in iodine chemistry. Dr. Solomon Fineman reviewed the roentgenograms. Valuable technical assistance was rendered by Elizabeth F. Focht, Ruth Hill, George Ross, Louella Tulip and Dr. A. A. Yalow.

similar to the response already described[6] in the literature on ordinary thyrotoxicosis or hyperthyroidism. This indicates that thiouracil suppresses hormone production by functioning metastases from adenocarcinoma of the thyroid as readily as it inhibits this process in the hyperplastic thyroid of ordinary hyperthyroidism.

Since [illegible] thyroid cell, normal or malignant [illegible] between inert and radioactive iodine, we are utilizing the normal affinity of this cell for iodine as a method of "selective irradiation" of a type of carcinoma of the thyroid. We now report the results of three years' study of the therapeutic effect of radioactive iodine in 1 case of metastatic carcinoma of the thyroid, in which all demonstrable metastases were shown to pick up radioactive iodine.

Radioactive iodine, as used in this and similar studies, consists of a mixture, in varying proportions, of two isotopes, I^{131}, half life 12.6 hours, and I^{131}, half life 8.0 days, prepared in a cyclotron by the bombardment of tellurium with deuterons. These two isotopes are chemically identical with stable iodine and cannot be separated by ordinary chemical or physiologic methods and processes. Both I^{130} and I^{131} emit beta rays (high speed electrons) which cause intense ionization within a few millimeters of tissue, as well as gamma rays which cause a negligible amount of ionization within the body and are sufficiently penetrating to be detected readily by an external Geiger counter.

REPORT OF CASE

Observations Prior to Radioactive Iodine Therapy.—Thyroidectomy: B. B., a man aged 51, had in 1923, at the age of 30, undergone a thyroidectomy because of substernal goiter and pressure symptoms on the trachea. He had no thyrotoxicosis. The histologic diagnosis was "malignant adenoma."

Pathologic Report: The pathologic report gave a gross description of three pieces of tissue received. The first one measured 5 by 5 by 3 cm. It was firm in consistency, and the cut section showed a fairly dense central core of connective tissue. No cystic or hemorrhagic areas were observed. The outer portion of the section disclosed a brownish yellow semipurulent material. The remaining two pieces of tissue were relatively the same in general structure but averaged about 2.5 cm. in thickness.

On microscopic examination, sections of the goiter showed no normal structures. Sections of tissue revealed definite fibrous change and there was an abundant pinkish hyaline-like stroma manifesting cell formation. There was a definite, highly atypical epithelial overgrowth which showed abundant growth and a tendency toward cord formation. In these areas no acini resembling the normal were seen. The nuclei of the cells took a rich blue stain. The growth showed no definite capsule surrounding it. Areas showing cartilage formation were present. No hemorrhage or infection was observed.

Recurrence and Laminectomy: Postoperatively there were no symptoms of hypothyroidism. The patient was in apparent good health for fifteen years. Then there developed palpitation, nervousness, loss of weight and signs typical of hyperthyroidism. In addition, *severe pains developed in the lower back* and radiated down the legs. On examination at another hospital in October 1939, a small pulsating tumor was found in the midline of the back at the level of the twelfth thoracic vertebra. Visualization by injection of diodrast showed the tumor to be extradural and extraosseous. Roentgenograms of the skeleton revealed no osseous lesions. The basal metabolic rate was + 40 per cent. A laminectomy was performed in November 1939. The tumor proved to be *a metastatic carcinoma of the thyroid* (fig. 1).

The histologic report revealed that the slide[7] showed several large ragged fragments of tissue, one of which contained spicules of bone and consisted of irregular cellular areas formed by broad hyalinized stroma bands. The general pattern was the same in all portions and consisted of irregular, often elongated, closely packed follicles with infoldings of the lining epithelium which varied from cuboidal to low columnar. There was no well formed stroma. Traces of granular colloid-like material were present in some follicles. In some areas the follicles appeared to have atrophied leaving the hyalinized-like bands previously mentioned. There were large areas of necrosis and some foci of hemorrhage. No mitosis was seen. The nuclei were fairly regular, dark and vesicular. The diagnosis was metastatic adenocarcinoma of the thyroid.[8]

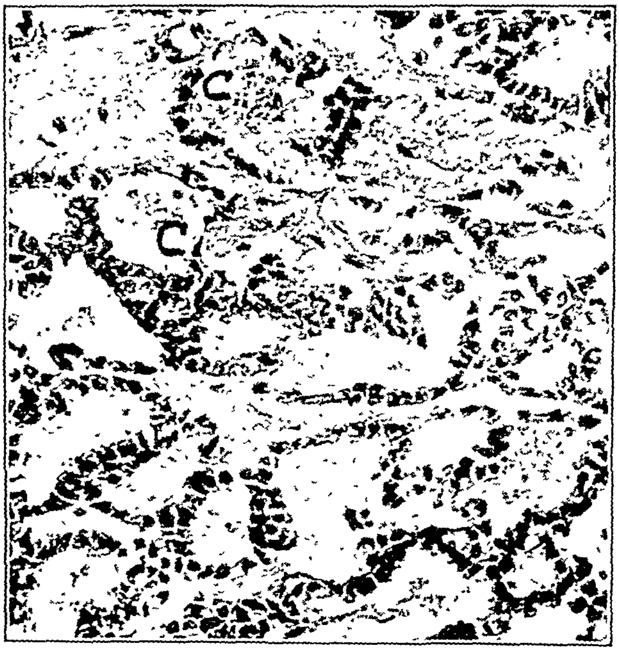

Fig. 1.—Photomicrograph of metastatic tumor in the twelfth thoracic vertebra magnified 400 times. Note follicular architecture and traces of granular colloid like material (*c*) in some follicles.

Treatment and Course: A thyroid crisis developed postoperatively. A few weeks later an exploratory operation was performed in the region of the thyroid and no thyroid tissue, normal or malignant, was found. Because of continuing pain, physiotherapy was given to the patient. In the next two years the symptoms and signs of hyperthyroidism increased. In December 1941 the basal metabolic rate was + 45 per cent. In addition, roentgen ray films of the lungs revealed "numerous circular deposits in the lower lobe on the left side and in the cardiohepatic angle on the right side, strongly suspicious of metastatic lesions." There was also radiographic evidence of destruction of the right upper femur (1.0 by 2.0 cm.) and the second rib on the left side. A gastrointestinal roentgenologic series was negative. A film of the pelvis taken at this time was reported negative for metastases, but our subsequent review (1946) of the plate revealed a small area (0.6 by 1.8 cm.) of early destructive changes in the inner border of the left ileum, above the acetabulum, just below the incisura ischiadica major. From December 1941 to February 1942 high voltage roentgen therapy was administered[9] as follows: dorsolumbar spine, 4,060 r; right upper femur, 3,180 r delivered through three fields. This course of therapy did not produce any symptomatic improvement.

Radioactive Iodine Therapy.—Observations at Hospitalization: On admission to Montefiore Hospital on April 20, 1942, the patient still had symptoms of pain in the lower part of the spine, in addition to the previously mentioned symptoms of hyperthyroidism.

The physical examination showed a rather small, emaciated, poorly developed man, aged 48, weight 38 Kg. and height 146 cm.; he was hyperkinetic, his blood pressure was 128 mm. of mercury systolic and 50 diastolic; his pulse rate was 100 to 110. There were no eye signs. There was a thyroidectomy scar in the neck, and no thyroid tissue was palpable. The heart was normal except for tachycardia. The lungs were clear. There was a laminectomy scar and tenderness over the dorsolumbar spine. The eye grounds were normal. The skin was warm, and there was a coarse tremor of the hands. The basal metabolic rate on May 7, 1942 was + 36 per cent. The plasma cholesterol about this time was 114 mg. per hundred cubic centimeters and the blood iodine[10] soon thereafter was 11.9 micrograms per hundred cubic centimeters.

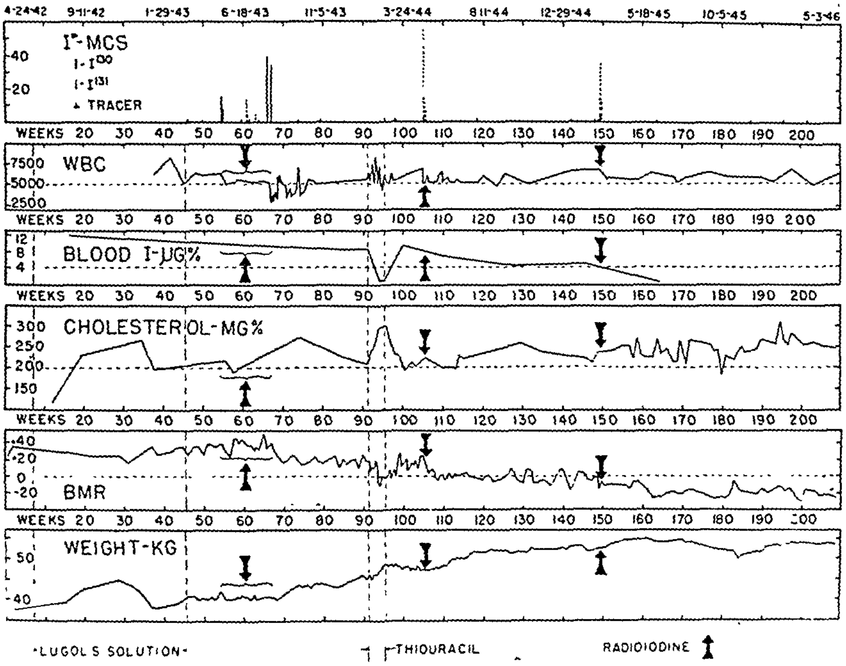

Fig. 2.—Response of clinical criteria to the administration of I^*.

Other laboratory examinations revealed nothing of special significance. The blood chemistry tests showed calcium, 10.3 mg., and phosphorus, 3.9 mg. per hundred cubic centimeters; phosphatase (alkaline) 12.2 Bodansky units; total serum protein, 6.7 Gm.; serum albumin, 3.2 Gm.; serum globulin, 3.5 Gm., and uric acid, 3.9 mg. per hundred cubic centimeters. The Wassermann and Kahn tests were negative; the blood count was within normal limits. Urinalysis was negative. The Ewald test showed free hydrochloric acid, none; combined acid 20 per cent.

A roentgenologic examination of the chest on April 25, 1942 revealed several rounded shadows suggestive of metastases in the lower lobe of the left lung; an extensive destructive lesion (5 cm. long) which involved the lateral and posterior aspect of the second rib on the left side; a circumscribed shadow (3.2 by 1.1 cm.) in the left infraclavicular region, which seemingly arose from the involved rib and represented a soft tissue mass. A picture of the dorsolumbar spine on Nov. 10, 1942 disclosed evidence of laminectomy; the spinous processes of the eleventh and twelfth thoracic vertebrae and the first lumbar vertebra were missing, and osteoporosis involved all the vertebrae. The pelvis on April 25, 1942 showed a small area of bone absorption (0.6 by 2.3 cm.) along the medial aspect of the left ileum above the acetabulum. The femurs on Oct. 29, 1942 presented a small area (larger than in films of December 1941) of bone absorption in the cortex of the right femur just below the lesser trochanter.

In view of the evident hyperthyroidism, iodine as Lugol's solution was administered every day in doses varying from 1 to 6 cc., from June 13, 1942 to March 8, 1943.[5]

As shown in figure 2, a mild remission in the hyperthyroidism occurred in response to the iodine therapy. By January 1943, iodine given as Lugol's solution in doses of 3 to 4 cc. a day lost its effectiveness even in regard to the hyperthyroidism itself, and its continued administration produced little further improvement.

The lesions of the bone continued to grow, and pain persisted. Another course of roentgen therapy was instituted as follows: right upper femur 3,260 r through two fields, and left pelvis 1,985 r through two fields. There was no relief of pain.

Administration of Radioactive Iodine: In March 1943 a tracer dose of radioactive iodine was given orally in the form of sodium iodide in water. This method of administration has been used for all doses. Geiger counter measurements revealed iodine retention by all the known lesions plus two previously unsuspected ones (fig. 3); one in the skull and one, not evident in the roentgenograms, located in the region of the ischium. During the taking of Geiger counter measurements, the patient asked that the counter be placed on the right parietal part of his head, for, he stated, there is a pain there which "is not a headache." Surprisingly, the counter registered the uptake of radioactive iodine. A subsequent roentgenogram (May 18, 1943) of the skull was reported as disclosing a fairly sharply circumscribed area of bone rarefaction (3.7 by 3.5 cm.) in the right posterior parietal region. At this time an exhaustive study of radioactive iodine uptake in the neck was made, and no evidence of residual functioning thyroid tissue could be established (see later comment). Due to technical difficulties, no attempt was made to study the radioactive iodine content of the lung metastases reported by the roentgen ray diagnostic department.

Measurements on urine after several tracer doses revealed that the patient excreted a relatively small amount (30 per cent to 40 per cent) of the tracer dose over a seventy-two to ninety-six hour period. The first course of radioactive iodine therapy, a total of 102 millicuries of the 12.6 hour isotope (I^{130}) and 20.5 millicures of the 8 day isotope (I^{131}), was administered between May and August, 1943 (see the accompanying table). The estimated radiation dose[11] to the tumors was 10,600 equivalent r,[12] whereas that for the blood was 70 equivalent r.

Since this course was administered in fractions of varying potency, it was possible to determine the effect of the different radiation doses on the leukocyte count. The I^{131} had no significant effect while the I^{130} had a considerable, though temporary, depressing influence (fig. 2) The expanded curve, figure 4, shows that after one dose of 40 millicuries of I^{130} the white blood cell count dropped from 5,150 to 2,900 in one week The blood count returned to normal in ten days even though another dose of 35 millicuries of I^{130} was given while the count was low

---

[9] Radiation dosages in this paper refer to tumor doses exclusively. Tumor depths were estimated from roentgenograms. Data used here were obtained from Rosh, R., and Raider, L.: Radiation Therapy of Carcinoma of the Thyroid, Radiology **44:** 556-564 (June) 1945 and a personal communication from Dr. Rosh.

[10] Baumann, E. J., and Metzger, N.: On the Amount of Iodine in the Blood, J. Biol. Chem. **121:** 231-234 (Oct.) 1937.

[11] This dose and the following therapeutic doses are calculated on the basis of an effective tumor volume of 312 cc. (vide infra) and on the basis of I^* (I^* refers to radioactive iodine without specifying the isotope) retained; that is, that administered minus that excreted in the urine. The possible change in effective tumor volume with time has been neglected. It would have been preferable, and is planned in the future to estimate tumor dose by actual measurements in vivo.

[12] Equivalent roentgens as used herein are defined and discussed in Marinelli, L. D.: Dosage Determinations with Radioactive Isotopes, Am. J. Roentgenol. **47:** 210-216 (Feb.) 1942.

The resulting improvement in the patient's clinical picture was definite in the course of the next few months By November 1943 the pains diminished, the basal metabolic rate dropped from an average level of above + 35 per cent to about + 20 per cent, the patient gained about 7 Kg in weight and roentgenologically there was no demonstrable growth of the metastases

Biopsy On Nov 6, 1943, a dissection biopsy of the metastasis in the second rib on the left side was performed by Dr. A H Aufses In order to obtain a radioautograph of this lesion and to ascertain the radioactive iodine concentration in the tumor tissue, a large tracer dose of I^{131} (5 millicuries) was administered eight days before the operation To remove the tumor on the second rib on the left side it was necessary to perform a scapula-mobilizing incision, with incision through the muscles of the posterior chest wall The postoperative course was uneventful, and the patient made an excellent recovery

Several radioautographs of the biopsy specimen were obtained by following in general the technic already described by Hamilton[2] Figure 6 shows a representative radioautograph and figure 7 is the eosin and hematoxylin stained section from which it was made A superimposition[13] of these two photographs is shown in figure 8 A detailed comparison between radioautograph and photomicrograph shows specific localization of the radioactive iodine within the regions of viable thyroid tumor cells

The total iodine content per gram of dry tissue of the biopsy specimen was 0.192 mg with a thyroxin fraction of 17.4 per cent The radioactive iodine content of the tumor tissue at the time of the biopsy was determined on four separate fresh specimens, weighing 0.28, 0.17, 1.49 and 2.05 Gm, respectively. The results were 0.18, 0.16, 0.19 and 0.20 per cent of the administered dose per gram of wet tissue[14]

From these figures and from the total urinary excretion up to the time of the biopsy it is possible to calculate the apparent tumor weight in the patient, assuming that the iodine concentration is uniform throughout the metastases and that no appreciable radioactive iodine is present in nontumorous tissues This value is 312 Gm. It is interesting to note at this point that an independent calculation of the tumor volume based on the contour of the metastases in the roentgen ray films agrees with the above value

A comparison of the biopsy tissue (figs. 5 and 9) with a section of the tissue removed on laminectomy in October 1939 (fig. 1) revealed close similarity.

Pathologic Report. The pathologic report was as follows On macroscopic examination the fresh specimen was an oval mass measuring 7.5 by 4.3 by 2.5 cm. and weighing 41.9 Gm. It was enclosed in a grayish white capsule about 0.5 cm thick on the surface of which there were, in places, some fibrofatty tissue and muscle. Attached to the capsule on one surface there was a piece of rib measuring 3.5 cm. in length to which was attached some fragments of muscle and fascia The mass was moderately soft, rather rubbery in consistency. On section, the tissue presented a mottled appearance, predominantly pale brownish with small and larger irregular dark red areas of congestion and hemorrhage, small translucent gray and yellowish foci and a few small, opaque, yellowish areas, probably of necrosis Some thin grayish white strands of fibrous tissue could be seen running through the mass The portion of rib attached to the mass was invaded on its adherent surface by tumor similar to and continuous with that of the mass, and fine bony spicules could be palpated in the latter for a distance of 1 cm or more from the rib

Microscopic examination revealed that the specimen consisted of sections of the tumor fixed in solution of formaldehyde and in Orth's solution and of decalcified portions of the tumor which included invaded rib. The tumor was surrounded by a thick capsule of dense fibrous tissue covered by fibrofatty tissue containing striated muscle fibers as well as some nerves and thickened arteries The muscle fibers showed considerable atrophy and degeneration. Occasional focal infiltrations of small round cells were seen The rather extensive hemorrhage in the capsule and surrounding tissue was probably largely traumatic. There was slight invasion of the capsule by tumor in a few places In all sections the central two thirds or more of the tumor showed

[13] This composite photograph was made by John M. Walke of the Physics Department of Memorial Hospital

[14] Dr Albert Keston made an independent determination on two of the specimens

extensive necrosis, hemorrhage and edema. This portion of the tumor consisted largely of fibrinous material which in areas was loose and fibrillar and in other places, dense and hyaline-like. Mixed with this in varying amounts were edema fluid, red blood corpuscles and in a few foci, necrotic and disintegrating polymorphonuclear leukocytes. Small and larger foci of viable tumor, frequently compressed, distorted and degenerating, were also seen in this central area. In places bands of edematous and hyaline-like stroma covered by flattened cells separated islands of fibrinous material, and in other places spindle cells growing in this material suggested organization. The peripheral, viable portion of the tumor disclosed little variation in architecture. It consisted of well differentiated follicles which disclosed considerable variation in size and shape but were predominantly small. The larger ones frequently showed infoldings and occasionally buds of new follicles in the walls. Some were widely dilated and others, compressed and slitlike. The follicles were lined for the most part by fairly uniform large cuboidal cells and in many instances by columnar cells. These cells had abundant acidophilic cytoplasm and fairly large, round, usually central but frequently basal, vesicular and hyperchromatic nuclei with fairly large nucleoli. No mitotic figures were seen. The nuclei on the whole were uniform, but an occasional large hyperchromatic nucleus was seen as well as occasional small pyknotic ones. In large areas the abundant cytoplasm was deeply acidophilic, and the cells resembled the so-called Hürthle cell. In some areas distended follicles were lined by low cuboidal or flattened epithelium. Although most of the follicles were empty or contained some red blood corpuscles and fibrin-like material, a considerable number contained a homogeneous colloid-like material which took a pale pink stain. In some areas the follicles were closely packed and separated only by narrow strands of connective tissue which contained many thin-walled sinusoid-like vascular channels, frequently engorged. In other areas the connective tissue septums were widened by edema and hemorrhage so that the follicles became widely separated. In still other areas there was appreciable fibrosis with atrophy of follicles; the fibrous tissue was cellular in some foci and partly hyalinized in others. Numerous hematoidin crystals were present in areas of recent hemorrhage. A few spicules of bone, some of them necrotic, were seen deep within the tumor.

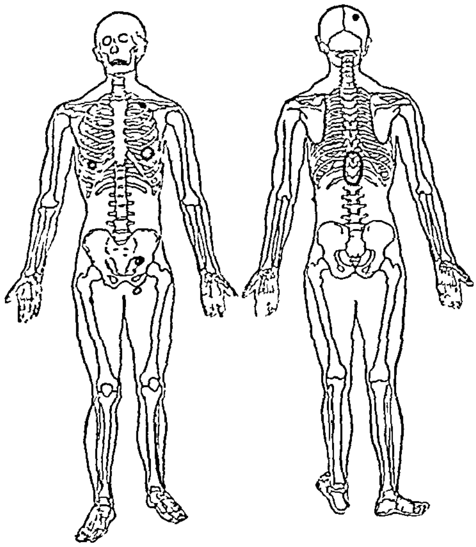

Fig. 3.—Location of metastases; solid black areas indicate osseous lesions, open circles indicate extraosseous lesions.

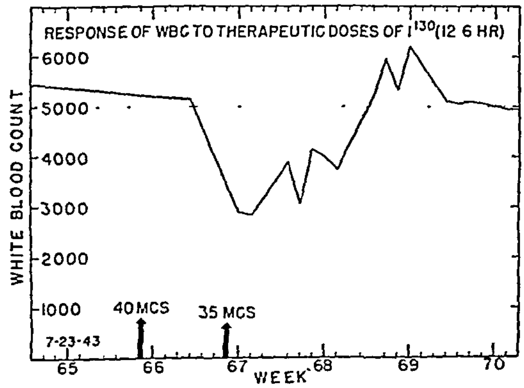

Fig. 4.—Effect of large amounts of I^{130} on the white blood cell count.

Sections taken through rib and adjacent tumor showed invasion of the bone by tumor with replacement of the marrow by a loose connective tissue. There was active formation of new bone, usually by apposition on old trabeculae, together with a lesser degree of osseous destruction. Spicules of bone were seen deep within the tumor itself; some of them were new bone arising from connective tissue septums. Similar new bone formation from connective tissue was seen in one place in the capsule.

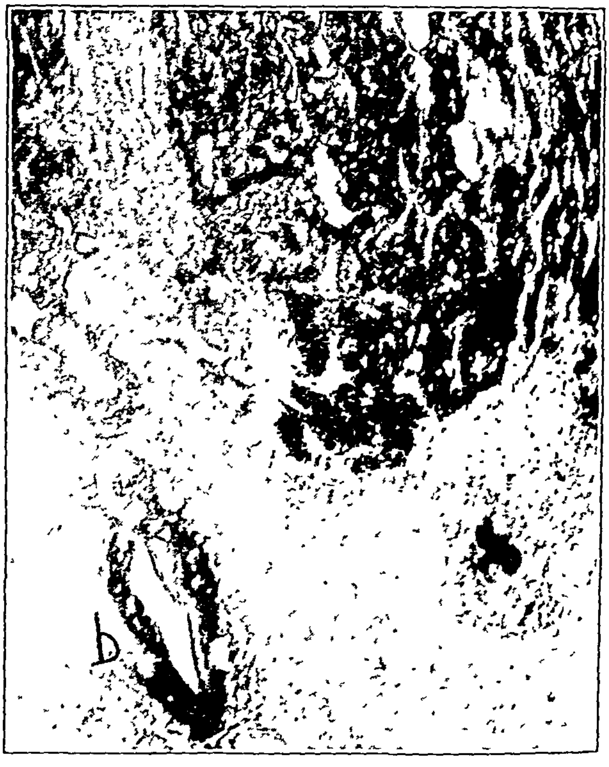

Fig. 5.—Circled area in figure 7 slightly reduced from a low power magnification of 25 times. Note narrow zone of viable tumor around blood vessel (*b*) which showed uptake of radioactive iodine in figure 6.

The diagnosis was metastatic thyroid adenocarcinoma of the differentiated small follicle type.[15]

Subsequent Treatment and Course: From Jan. 23 to Feb. 21, 1944, the patient was submitted to a course of treatment with thiouracil. This was done to check further on the functional nature of the metastases. The thiouracil therapy produced a striking remission of the hyperthyroidism, which, however, promptly recurred after the treatment was discontinued. The effect of thiouracil on the objective criteria of hyperthyroidism is shown in figure 2.

By the end of April 1944 the patient's condition had reached what might be called a state of equilibrium. His weight remained unchanged for two months at the level of 48 Kg, with basal metabolic rate at about + 10 per cent and the plasma cholesterol level between 200 and 214 mg. per hundred cubic centimeters The blood iodine on March 24 was 9 4 micrograms per hundred cubic centimeters Roentgenograms taken on April 21, 1944, showed no detectable changes in the various metastases The second therapeutic dose of radioactive iodine, 55.4 millicuries of the eight day isotope, was administered on April 28, 1944 Twenty-seven per cent of this dose (13.8 millicuries) was extracted from a twenty-one hour urine collection[16] and readministered on April 29. A second fraction from urine was obtained later (6 3 millicuries) and readministered on April 30 Thus a total of 75 5 millicuries was administered within three days, giving a radiation dose of 18,200 equivalent r to the tumor and 64 equivalent r to the blood. The white blood cell count showed only a slight temporary fall from 6,000 to 4,500, which, in our opinion, was not significant The basal metabolic rate dropped to zero in about three weeks and remained at about this level until March 1945. The plasma cholesterol fluctuated from a level of about 200 mg. per hundred cubic centimeters to a somewhat higher level. The blood iodine level dropped to 6 5 micrograms on June 10, 1944, to 4 7 micrograms on Oct 7, 1944 and to 5 1 micrograms per hundred cubic centimeters on Feb 8, 1945 The patient's weight began to rise about three weeks after the administration of the therapeutic dose of radioactive iodine and continued to rise steadily from 48 Kg in April 1944 to 53 Kg in January 1945 Shortly after this second therapeutic dose of radioactive iodine a temporary sharply circumscribed alopecia appeared over the area corresponding to the skull metastasis The patient's general well-being improved, his pains diminished, his locomotion improved, and he complained of getting fat. Roentgenograms on Aug 19, 1944 and Feb. 6, 1945 showed no change

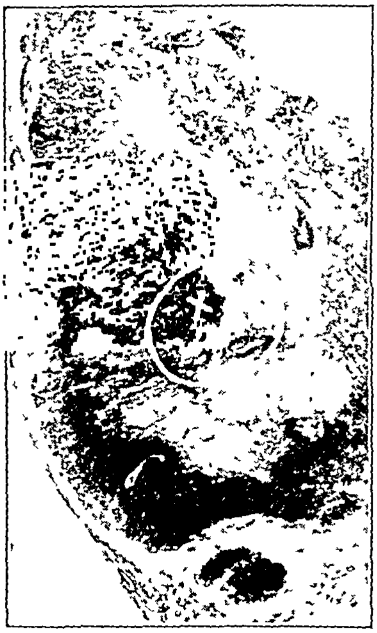

Fig 7—Photomicrograph of section used for figure 6 stained with eosin and hematoxylin, same magnification Note viable (dark) and necrotic (light) areas.

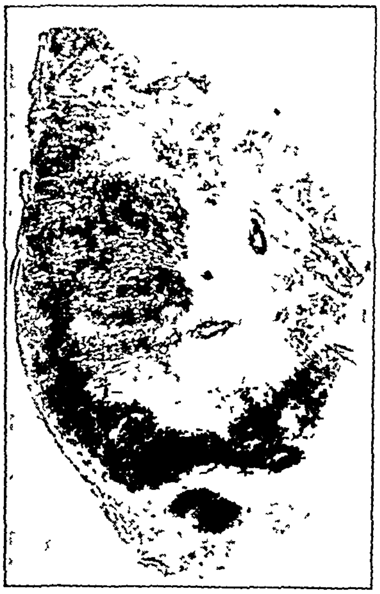

Fig 8—photograph of figures 6 and 7 superimposed, showing coincidence of radioactive iodine distribution with the viable tumor

From Feb 8 to 25, 1945, the patient was given intramuscular injections of thyrotropic factor (Armour's; Rowlands-Parkes' units per cubic centimeter) The injections were given in divided doses every one or two days for a total of 33 cc in eighteen days During this interval of treatment there was no rise in the basal metabolic rate, no significant change in plasma cholesterol and a slight fall in blood iodine (from 5.1 to 4 1 micrograms per hundred cubic centimeters). Bioassays of the urine for thyrotropic hormone[17] both before and during the interval of this treatment were negative, indicating that the patient's own thyrotropic hormone was inactivated by the tumor tissue.[18]

On March 3, 1945, the third therapeutic dose of radioactive iodine was given It consisted of 41 6 millicures of I^{131} plus 16 0 millicuries recovered from the urine and fed three days later. The total of 57 6 millicuries gave a tumor dose of 11,600 equivalent r, a blood dose of 41 equivalent r. The patient's weight increased and the basal metabolic rate, which was in the normal range immediately before the treatment, dropped to —27 per cent in about three months and has remained consistently low The plasma cholesterol increased slightly and has remained above the pretreatment level. The blood iodine dropped from 4.1 micrograms per hundred cubic centimeters immediately before this third therapeutic dose to 0 8 microgram per hundred cubic centimeters three months later.

The patient's general condition is good. He moves freely about the hospital and is engaged in occupational therapy.

COMMENT

Adenocarcinoma of the thyroid is generally considered highly radioresistant. H. F. Hare[19] specifically stated that alveolar carcinoma of the thyroid is not changed histologically by 6,000 r (x-ray). For a successfully treated patient (his case 2) Hare gives the dimensions of the tumor and the interstitial radon dose employed. Calculations show the gamma ray dose to be close to 20,000 r, a value well beyond the reach of external radiation.

---

[16] Dr. E J Baumann, Chemistry Department, Montefiore Hospital, developed a procedure for extracting iodine from urine so that it could be refed to the patient in the form of sodium iodide This technic was utilized whenever the amount of I* involved warranted it The efficiency of recovery was consistently high, 80 to 95 per cent

[17] Determinations were made on young guinea pigs weighing 200 Gm, using total weight of thyroid gland and degree of hyperplasia as criteria Extraction of thyrotropic hormone from the urine followed the method described by Jones, M. S · Study of Thyrotropic Hormone in Clinical States, Endocrinology **24**: 665 671 (May) 1939

Since 1 microcurie of 8 day iodine destroyed per gram of tissue gives approximately 150 equivalent r,[20] to achieve comparable dosage we must concentrate at least 133 microcuries in each cubic centimeter of tumor, if turnover is assumed to be zero. For our patient, with approximately 300 cc. of tumor tissue, such a dose would require that 40 millicures of I^{131} be fixed in the tumors. The actual amount to be fed, however, may be several times this amount, because of the loss of iodine by excretion and by deposition in other tissues, especially if normal thyroid tissue is present.

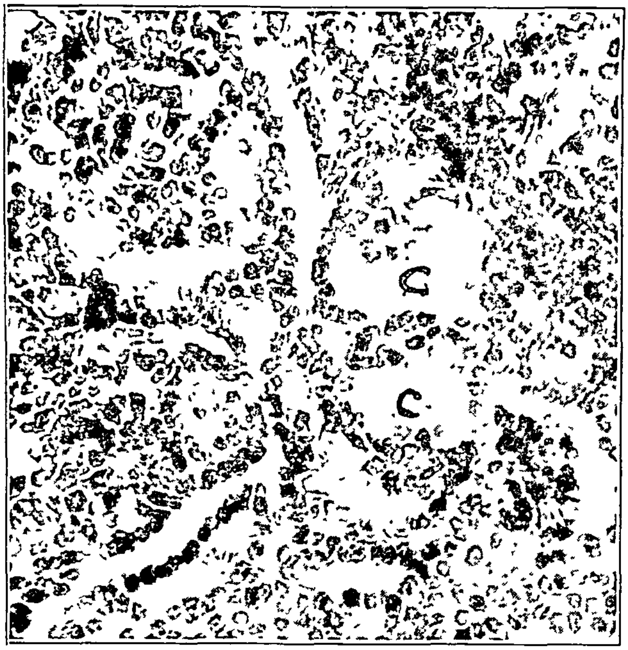

Fig. 9.—Higher magnification (400 times) of section taken at X in figure 7. Note follicular structure and colloid like material (*c*) in a few follicles.

In addition to these rough quantitative considerations, criteria of a biologic nature, such as the time factor and lack of irradiation of the tumor bed beyond a few millimeters, must be considered in comparing the results of 8 day iodine beta ray therapy with those of 3.82 day radon gamma ray therapy. These remain to be assessed on the basis of additional experience.

Over a period of three years, our patient has received nearly 40,000 equivalent r to each of his tumors. In spite of the remarkable clinical improvement, it cannot be concluded that the functioning tumors have been completely destroyed because recent tracer studies, although showing a marked increase in excretion, still show localization of radioactive iodine in the lesions. Further therapy is indicated and is being planned, the limiting factor being the availability of the isotope in sufficient quantity. The criterion for completion of I* therapy will be the lack of radioactive iodine pickup by any of the known metastases, although the possibility remains that the tumors, even in the absence of any uptake, will not be completely destroyed.

All available roentgenograms taken of this patient since July 1939 were reviewed recently in order to evaluate as precisely as possible the progress of the various skeletal lesions. Between July and October of 1939, films were made of the spine, pelvis, skull, arms, legs and left femur. At this time all the regions were negative for metastases. In November 1939, the extraosseous metastatic tumor in the back was removed. By 1941 there were early lesions in the right femur, right ileum and chest as described in the case history. These lesions increased in size, and the one in the skull was discovered in 1943. Frequent plates were taken of all these regions from 1942 until the present, and they show that there was no increase in the area of bone destruction in any region after the first therapeutic dose of I^{131} was administered in 1943. Representative films showing the progress of three of the lesions are shown in figures 10, 11 and 12.

The urinary excretion of radioactive iodine was followed after almost every dose, tracer or therapeutic; on several occasions the collection period was longer than a month. As an illustration, the data obtained after the dose of Aug. 5, 1943, is shown in figure 13. Plotted on semilogarithmic paper, the curve shows two distinct, consecutive rates of change in daily excretion, the break occurring three days after administration. In the same figure a second curve is shown which represents the daily excretion of radioactive iodine by this patient soon after the cessation of thiouracil therapy. The data as a whole seem consistent with the hypothesis that in both instances the excretion of radioactive iodine within three days of administration is governed by a mechanism different from the one which governs its excretion thereafter.

The concentration of radioactive iodine in the blood as a function of time was studied in order to gain information of physiologic and radiologic significance. Shown in figure 14 is a composite curve obtained after the administration of the last two therapeutic doses of radioactive iodine (April 28, 1944; March 3, 1945). The individual determinations pertaining to each study are shown in detail. The data of Frantz and her associates[1] are also shown for comparison. From the curve it is seen that the level of I* in the blood

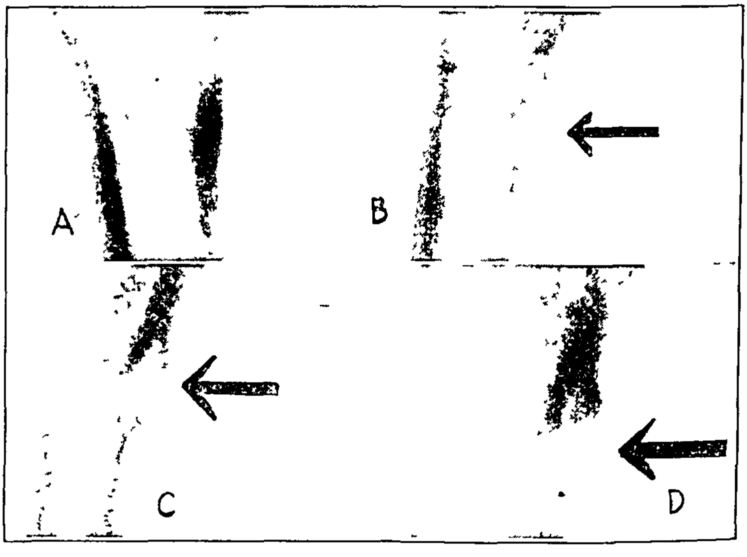

Fig. 10.—Roentgenologic appearance of lesion of the femur on *A*, Oct. 30, 1939, *B*, Oct. 29, 1942, *C*, June 22, 1944, and *D* (a higher magnification), May 22, 1946.

---

[20] A complete description of experimental methods and calculations will be given in a companion paper now in preparation.

remains essentially constant for a considerable period after the first day. An analysis of the detailed data obtained on this particular patient indicates that the curve represents three different phases; a rapid initial turnover (about twenty-four hours) which is succeeded by a stabilized level of one week's duration, and finally, a slow but steady decline.

Many authors have reported significant drops in the white blood count after the administration of radioactive isotopes other than iodine. Our experience with large doses of radioactive iodine shows that with this element the effects on the white blood cells are not pronounced and are short-lived. A drop in total leukocytes with no significant variation in the differential was observed after the administration of large amounts of I^{130} but not after the use of I^{131}, although the total blood dosages were comparable in magnitude. However, since radiation from the 12.6 hour isotope is delivered almost entirely within two days, whereas from the 8 day isotope nearly the same proportion is delivered within thirty-two days, we must infer that the time factor is mainly responsible for the previously stated results. This is analogous to many other radiobiologic phenomena such as erythema production with single and fractional roentgen therapy, in which time is an important factor.

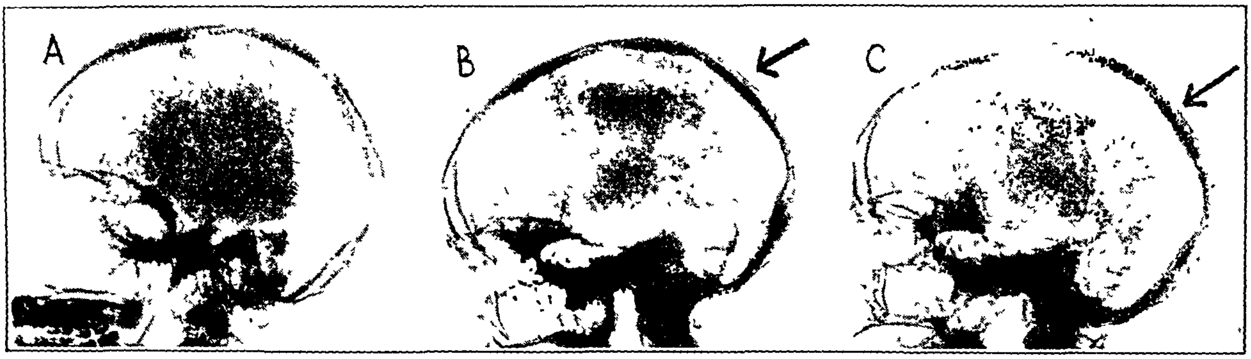

Fig 11.—Roentgenologic appearance of lesion of the skull on *A*, Oct. 30, 1939, *B*, May 18, 1943, and *C*, Feb 4, 1946

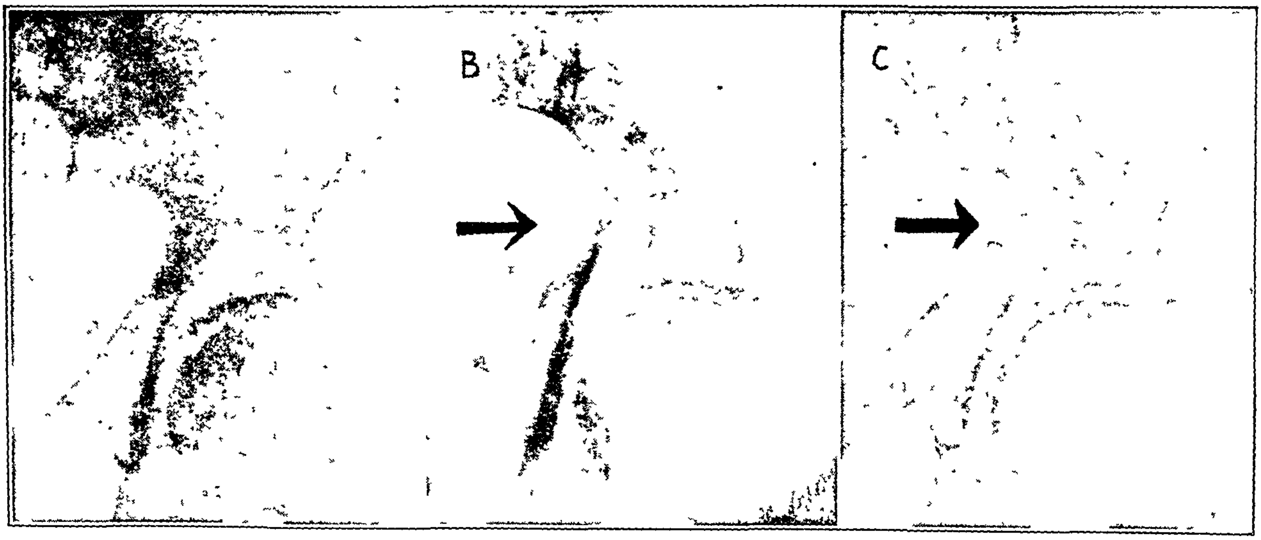

Fig 12.—Roentgenologic appearance of lesion of ilium on *A*, July 17, 1939, *B*, Nov 10, 1942, and *C*, May 22, 1946

It is logical to assume that the effect of this factor on tumor tissue will be in the same direction as it is on the blood. Therefore, consideration of the time factor alone might seem to contraindicate the use of I^{131} in the treatment of tumors because higher doses would be required to obtain a given effect. The value of radiation treatment, however, must be based on the differential effect on both tumor and normal tissue. It can be shown for oral administration of the isotope that the ratio of the tumor dose[21] to the blood dose is about 80 when I^{130} is used and about 300 when I^{131} is used. Thus, the use of I^{131} would be approximately four times as effective as the use of I^{130} if there were no time factor involved. To offset this advantage the differential time factor would have to render the 12.6 hour isotope more than four times as effective for a given blood dose as the 8 day isotope before there could be a question about the advisability of the use of I^{131} in preference to I^{130}. This remains to be determined.

In earlier studies[22] of thyroid-iodine metabolism by the use of I^* it was shown that irrespective of the total amount of iodine administered, the hyperactive gland initially retains more I^* than the normal gland but loses it faster. The rate of loss seems to increase with larger amounts of carrier iodine.

With this in mind as well as with the purpose of determining ultimately the actual radiation dose delivered to the tumors, the I * turnover in the lesions was studied by means of suitable Geiger-Mueller counters under reproducible geometric conditions. This was done several times between May and August 1943, as well as ten months and one year after the third therapeutic dose. Unfortunately, the 1943 measurements—due to circumstances partially beyond our control—cannot be interpreted without making some assumptions. The only thing that can be said is that several days after the administration of a tracer dose of I ^{131} the activity of all the lesions, when corrected for decay of 8 day iodine, disclosed the elimination of about 0.5 per cent of the dose per day. This observation per se cannot be interpreted as a demonstration that the tumor tissue metabolized I * at the rate of normal thyroid tissue, although this was our impression. The latest data (1946), figures 15 and 16, taken much more accurately, show a rapid loss of I * in the two lesions studied when 40 micrograms of carrier iodine was administered. With the larger amount of carrier iodine, the rate of loss was not as great, in proportion. We are unable to interpret these data in the light of published works on the turnover of I * in the thyroid itself.

---

[21] Calculated on the basis of the experimental curve of concentration of the I^* in the blood and a net tumor elimination rate of 0 5 per cent per day.

[22] Hertz, S., Roberts, A, and Salter, W. T.: Radioactive Iodine as an Indicator in Thyroid Physiology: IV The Metabolism of Iodine in Graves' Disease, J. Clin Investigation **21**: 25 32 (Jan) 1942. Hamilton.[2]

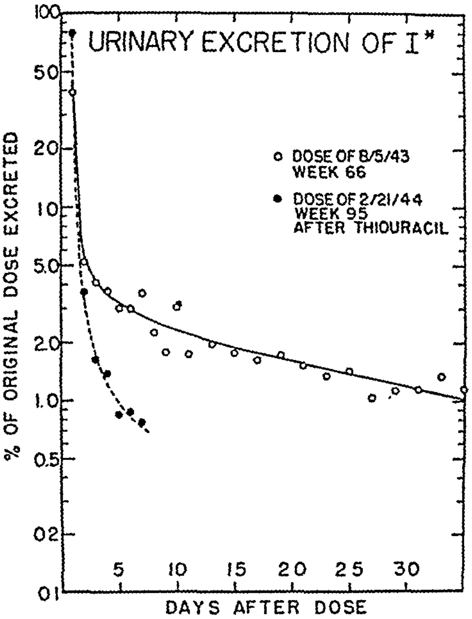

Fig. 13.—Typical trend of urinary excretion of I *.

Owing to the unusual nature of this case, that is, hyperthyroidism despite total thyroidectomy, the procedure and results of our studies of radioactivity over the region of the original thyroid as well as over the metastases may be of interest.

The experimental setup and the theoretic considerations will be described in detail in another paper. It suffices to state here that the Geiger counter is shielded with a ¾ inch (1.91 cm.) thickness of lead and provided with a suitable window. The activity of any lesion or region is obtained by taking the difference between readings with the window open and those with the window plugged with a ¾ inch (1.91 cm.) thickness of lead. This method greatly facilitates the localization of radioactive iodine in contiguous lesions.

The counter readings over the thyroid area were on the average only 5 per cent of the readings obtained over the metastasis of the skull. This percentage did not change materially throughout the course of the study. The readings over the thyroid region were two to three times the readings taken over the lateral surface of the right calf but consistently less than readings obtained over the apex of the right lung, although both regions were free from metastases. A comparison with 2 nonthyroidectomized patients under similar conditions of dosage and excretion showed that iodine pickup in this patient's thyroid region was only 4 per cent and 6 per cent, respectively, of the iodine pickup in the thyroid regions of the other 2 patients.

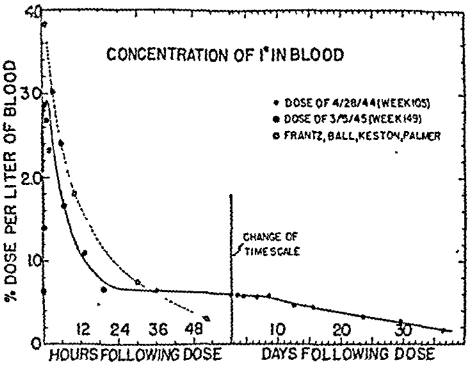

Fig. 14.—Concentration of I * in the blood (corrected for decay) after oral administration of the radioactive element.

While the evidence presented herein shows clearly that there was little activity over the thyroid region, it might be argued that since this activity was greater than that obtained over the calf, the existence of some residual thyroid tissue cannot be ruled out. However, the presence of functioning metastases in the neighborhood of the thyroid region will cause some scattered gamma radiation to enter the instrument. No similar condition exists in the region of the calf, which was first used as a control. But when, with this in mind, we chose as a control region the apex of the right lung—analogously situated with respect to the neighboring functioning metastases, but containing none—we obtained readings even greater than those in the thyroid region by 15 to 30 per cent.

The foregoing, in our opinion, is presumptive evidence that there is no functioning thyroid tissue in the neck and confirms the previous surgical observations.

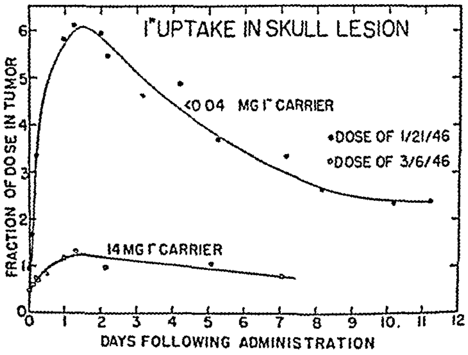

Fig. 15.—I * uptake in a representative lesion of the skull subsequent to the administration of doses containing different amounts of carrier iodine.

It is pertinent to mention that 4 cases of metastatic carcinoma of the thyroid without clinical hyperthyroidism have been studied with radioactive iodine and have shown selective localization in the lesions. Two of these are now under treatment with I.*

SUMMARY

A case of metastatic adenocarcinoma of the thyroid is reported in which treatment by means of radioactive iodine has been successful. The patient was completely thyroidectomized for "malignant adenoma" in 1923, with neither thyrotoxicosis then nor hypothyroidism postoperatively; fifteen years later there developed classic symptoms of hyperthyroidism and severe pain in the lower back. In October 1939 a pulsating tumor removed from the level of the twelfth thoracic vertebra proved to be metastatic thyroid adenocarcinoma (histologically well differentiated, with small follicles and colloid). In the next two years hyperthyroidism increased and roentgenograms revealed new metastases in the lungs, upper part of the right femur, second rib on the left side, left ileum and skull. Roentgenologic irradiation of the metastases proved ineffectual.

In March 1943 a tracer dose of radioactive iodine revealed iodine retention by all the known lesions and no evidence of residual thyroid tissue in the neck. Therapeutic amounts of radioactive iodine were administered orally between May and October 1943. Definite and lasting clinical improvement followed. In April 1944 and March 1945 additional I* was administered with a resultant disappearance of pain, increase in weight and progressive change in all clinical criteria in the direction of hypothyroidism. Roentgenographic evidence pointed to an arrest if not a regression of the disease. No untoward effects followed this therapy.

Radioactive iodine seems to be an effective therapeutic agent in the control of this type of tumor.

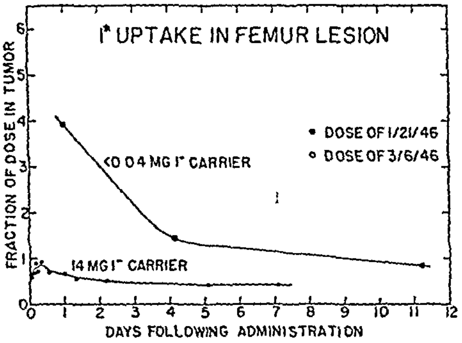

Fig. 16.—I* uptake in a representative lesion of the femur subsequent to the administration of doses containing different amounts of carrier iodine. The fraction of dose in the tumor is proportional to the ratio of counts obtained over the given lesion under fixed geometric conditions to counts obtained at the same time on an aliquot part of the administered I*. Thus, figures 15 and 16 represent correctly the time change in concentration in any one lesion, but because of the geometric differences involved in the measurements they do not permit direct comparison of the I* concentration in the two lesions.

Fundamental Research and the Rh Factor.—The fundamental basis for the recognition of the Rh factor was laid in 1900 when three important discoveries were made. First, the mendelian laws of heredity, published thirty-five years previously, were independently rediscovered by Correns, Tchermak and de Vries. Second, in the same year Landsteiner discovered the phenomenon of normal isoagglutination as the basis of the four blood groups, and in the next year he mentioned their significance in the selection of donors for transfusion. Third, and of more immediate importance, Ehrlich and Morgenroth discovered the phenomenon of isoimmunization, which they demonstrated in goat blood and which other workers later demonstrated in many species.—Levine, Philip, M.D.: The Present Status of the Rh Factor, *Am. J. Clin. Path.* October 1946.

TREATMENT OF EARLY SYPHILIS WITH CALCIUM PENICILLIN-OIL-BEESWAX

MAJOR MONROE J. ROMANSKY
Medical Corps, Army of the United States
and
CHARLES R. REIN, M.D.
with the Technical Assistance of Mr. George E. Rittman
Washington, D. C.

The early development and progress in the production of a suspension of calcium penicillin in beeswax and peanut oil has already been reported.[1] The initial successful clinical results in the treatment of gonorrhea [1c] by a single injection of this mixture suggested its use for the treatment of syphilis. It should be emphasized that the primary purpose of this paper is to illustrate an ambulatory method of therapy whereby the patient receives one injection of penicillin instead of the usual eight injections a day.

This study was initiated in August 1944. Since then 75 patients with early syphilis have been treated, of whom 72 were men and 3 women. The ages varied from 18 to 44. There were 37 white and 38 Negro patients. Fifty-six had primary syphilis, of whom only 6 were seronegative, while the remaining 19 had secondary syphilis. All patients were subjected to serologic examination prior to institution of treatment. Dark field examinations gave positive results in 73 patients. The remaining 2 gave a history of having had a penile lesion followed by the development of a generalized eruption and had persistent strongly positive serologic reactions for syphilis, but dark field examinations were not made. Before treatment 31 patients with primary syphilis and 16 with secondary syphilis had an examination of the spinal fluid, which included cell count, Kolmer complement fixation, total protein, globulin and colloidal gold tests. The 31 patients with primary syphilis had normal spinal fluids, while 4 of the 16 with secondary syphilis had abnormal spinal fluids.

The treatment consisted of the daily intramuscular (buttock, deltoid or triceps) administration of 300,000 units of calcium penicillin in beeswax and peanut oil for eight days.

Of the first 14 patients treated, 2 received 100,000 units three times a day, 2 received 150,000 units twice a day and 10 received 300,000 units in 2 or 3 cc. once a day. The remaining 61 patients received 300,000 units in 1 cc. The total number of Oxford units for all patients was 2,400,000 which is comparable to the

From the Penicillin Section and Medical Service, Walter Reed General Hospital, and the Department of Serology, Army Medical School, Army Medical Center (Mr. Rittman).

Major Romansky is now civilian consultant in antibiotics to the office of the Surgeon General, U. S. Army, and associate clinical professor of medicine, George Washington University School of Medicine, Washington, D. C.

Assistance was rendered by the following medical officers: Captain Robert J. Murphy, Captain Aubrey Harwell, Captain Samuel Katz, Captain Francis W. Epstein and Captain Merritt E. Roberts. Miss Mina Levy, Miss Dorothy Talbott, Miss Jewel Patton, Miss Lillian Axelrod, Miss Sarah McDearman and Sergeant Leslie H. Wood gave technical assistance.

practice of giving sixty injections in seven and one-half days for the same total.

The schedules of therapy for the first 14 patients were necessary since the potency of the then available calcium penicillin was inadequate to produce a mixture which would maintain satisfactory levels in the blood for approximately twenty-four hours after a single intramuscular injection. As soon as calcium penicillin with a potency of approximately 1,000 units per milligram was available, it was possible to suspend 300,000 units in 4.8 per cent beeswax (by weight) in peanut oil contained in 1 cc. As shown in a previous report,[2] this mixture will maintain satisfactory assayable levels in the blood for about twenty to twenty-four hours after a single injection and continue to be excreted in the urine for about three days. Patients 15 to 75, therefore, received the preparation consisting of 300,000 units of calcium penicillin in 4.8 per cent beeswax in peanut oil contained in 1 cc.

Blood was obtained at thirty minutes and at four hour intervals for twenty-four hours in order to determine the penicillin levels. During the subsequent seven days of therapy, blood was withdrawn at the twenty-fourth hour after injection for the same purpose. Specimens of urine were obtained for six days following the last injection in order, to determine for how long a period penicillin continued to be excreted. Dark field examinations were repeated at frequent intervals in order to determine the disappearance time of the spirochetes. Patients were also observed for the appearance of Herxheimer reactions. Daily inspections were made to determine the time of healing of syphilitic lesions. The patients were observed for a minimum of fifteen days, during which time additional specimens of blood were withdrawn for serologic examination. Blood was also withdrawn monthly for as long as possible. Each serum was subjected to a battery of six qualitative serodiagnostic procedures, including Kline diagnostic, Kline exclusion, Mazzini, Kahn and Kolmer tests as well as a new microflocculation test employing a cardiolipin antigen.[3] All serums which gave a four plus reaction with any of the foregoing procedures were also tested quantitatively by the same procedures.

Penicillin was continuously present in the blood during the eight days of therapy. Its presence in the urine for six days following the last injection indicated that penicillin was present in the blood for a total of fourteen days. When penicillin in aqueous solution is administered in sixty intramuscular injections of 40,000 units every three hours for seven and one-half days, penicillin will not be present in the blood at the end of the eighth day. This indicates that with the same total dosage (2,400,000 units) patients receiving the beeswax and peanut oil mixture may have the benefit of penicillin for an average of five to six days more than those who receive sixty injections of the aqueous solution.

The lesions were rendered dark field negative in ten to thirty-six hours after the initial injections of penicillin in beeswax and peanut oil. Fifty-two per cent were negative by the twelfth hour, 97 per cent by the twenty-fourth hour and the rest by the thirty-sixth hour.

In 39 per cent of the patients some degree of Herxheimer reaction developed, as evidenced by a slight to moderate rise in temperature. Ten per cent of these also had a concomitant cutaneous reaction, as manifested by exacerbation of an existing secondary eruption or the development of a rash.

Both primary and secondary lesions were healed in three to twelve days, with an average healing time of seven days.

Of the 75 patients treated, results for 60 are shown in the table. The remaining 15 patients could not be followed clinically or serologically for a sufficient length of time to be evaluated. These patients, however, are included, since they showed a satisfactory time for disappearance of the spirochetes and a rapid healing of primary and secondary syphilitic lesions. Forty (66.6 per cent) of the 60 patients attained and maintained seronegativity with all tests in the serologic battery for the period of follow-up. An additional 18 patients (30.0 per cent) showed satisfactory progress at the time of the last serologic examination. There was, therefore, a satisfactory response in 58 of the 60 patients followed. The results in 2 patients (3.3 per cent) with secondary syphilis are classified as failures. There were two reinfections. Both of the patients with reinfection had attained and maintained seronegativity following treatment. Thereafter, a new seronegative dark field–positive primary lesion developed. Serologic reactions subsequently became positive. Contacts with infectious syphilis were established in both instances.

Of the 40 patients who attained seronegativity, 37 had primary and 3 had secondary syphilis. It is interesting to note that all patients who became seronegative *within six months* had *primary syphilis*, whereas the 4 patients who were still seropositive (but had shown a satisfactory response) at nine or more months following therapy had secondary syphilis.

Some of the factors which determined the length of time required to attain seronegativity are as follows: (1) the stage of the disease at the time treatment was instituted (examinations of patients with primary syphilis gave negative results earlier than those of patients with secondary syphilis); (2) the serologic titer at the onset of treatment (examinations of patients with low-titered serologic reactions gave negative results earlier than those of patients with high-titered serologic reactions), and (3) sensitivity of the tests employed (tests with greater sensitivity maintained seropositivity for longer periods than did the less sensitive tests).

[3] Rein, C. R., and Bossack, H. N.: Cardiolipin Antigens in the Serodiagnosis of Syphilis: A Microflocculation Slide Test, Am. J. Syph., Gonor. & Ven. Dis. **30:** 40, 1946.

It is important that all patients receiving penicillin therapy be subjected to serologic examinations at frequent intervals (at least once a month) in order to detect serologic relapse and impending clinical relapse as early as possible. A serologic relapse usually precedes a clinical relapse by about one month.

Twenty-four hours after the intramuscular injection of penicillin in beeswax and peanut oil there was some soreness to pressure at the site. This was usually gone by the forty-eighth to seventy-second hour. This sequence of events occurred after each injection, although the injection was administered at a different site. The soreness was no severer than that following the multiple injections of an aqueous solution of penicillin, and the patient had the added advantages of being on an ambulatory basis and of receiving only one injection a day. It is not desirable to massage the site of injection, since diffusion of the material will accelerate absorption and increase local soreness.

Studies of tissue in animals and in human beings [4] from the sites of injection of calcium penicillin in beeswax and peanut oil show that, although the material may be injected subcutaneously, considerably less reaction occurs when it is given intramuscularly. Clinically, this is also true, as indicated by subjective and objective findings.[4a] This has also been corroborated by Nichols and Hauntz [5] but it is contrary to the report of Kirby and associates,[6] who stated that less discomfort occurs following the subcutaneous administration of penicillin in beeswax and peanut oil.

Two patients in this group had allergic reactions manifested by the development of urticaria five to six days following the eighth injection. The urticaria was similar to that seen after the use of an aqueous solution of penicillin and lasted for six to seven days, reaching its peak on the fourth day. The incidence of allergic reactions after the intramuscular use of calcium penicillin in beeswax and peanut oil is about the same as that following the use of an aqueous solution of penicillin by multiple injections or by other routes. Reactions at the site of injection are more frequent when penicillin in beeswax and peanut oil is given subcutaneously. The preceding conclusion is based on the treatment and study of approximately 500 patients given a single daily injection of calcium penicillin in beeswax and peanut oil for a variety of diseases.[4] No other untoward reactions were noted as a result of the administration of this mixture. Beta-dimethylaminoethyl benzhydryl ether hydrochloride (Benadryl), a new drug, is effective in most instances in alleviating the allergic manifestations produced by penicillin. We have also used it simultaneously with penicillin to prevent the allergic complications in patients who have previously been sensitive to penicillin.

The present preparations of calcium penicillin in beeswax and peanut oil present no difficulty in administration, since they can be administered with a 22 gage needle at room temperature (25 C.) if necessary. However, the practical needle for routine use is the 20 gage. This is best illustrated by the fact that over fifty thousand injections of this preparation have been given by the nursing staff at the Walter Reed General Hospital in the treatment of all conditions necessitating the use of penicillin. In the early preparations some trouble in withdrawal and administration was experienced. As a rule this was due to the occasional difficulty in properly blending the penicillin powder, with the result that the mixture was viscous and occasionally large particles obstructed the passage of the mixture through the needle. The method of administration has been reported previously.[2] However, one point should be emphasized. Once the material is drawn into the Luer-Locke syringe it should be allowed to cool to room temperature prior to injection. It is unnecessary to rewarm the syringe. In view of its stability, the calcium penicillin in beeswax and peanut oil can be kept at room temperature for at least a year.[7]

It has been stated previously [8] that because of the hygroscopic factor in the noncrystalline sodium salt the calcium salt must be used in the preparation of penicillin in beeswax and peanut oil mixtures. This is contrary to a recent report of Leifer and Kirby [9] who stated that the sodium salt may be used as well as the calcium. It has been observed that not only does the noncrystalline sodium salt produce erratic and less prolonged levels than the calcium but, more important, it does not maintain its stability.[10] Furthermore, there is a tendency for the particles of sodium salt to congeal into clumps in the beeswax and peanut oil mixture, preventing passage of the material through the needle. These difficulties may be obviated when crystalline sodium salt is available for the preparation of the penicillin-beeswax-peanut oil mixture.

The data presented indicate that early syphilis may be treated by the described ambulatory method, only one daily injection of penicillin being employed for eight days. We, as well as others, have encountered failures regardless of the penicillin schedule used. With the hope of reducing the number of such failures, we have initiated a study in which the same single dose of 300,000 units of penicillin is administered daily over a period of sixteen days for a total of 4,800,000 units. An additional group of patients with early syphilis is being treated on the same schedule with crystalline penicillin G in beeswax and peanut oil.

SUMMARY

1. An ambulatory method for the treatment of early syphilis is described. A single daily intramuscular injection of 300,000 units of calcium penicillin in 4.8 per cent beeswax in peanut oil contained in 1 cc. is administered for eight days.

2. Fifty-eight of the 60 patients thus treated and followed gave satisfactory results. Although the number of patients in this study is too small to be statistically significant, the results obtained with this method of therapy suggest a favorable trend.

ABSTRACT OF DISCUSSION

Dr. Donald R. Nichols, Rochester, Minn.: Mixtures of beeswax and peanut oil have been used successfully to prolong the action of several drugs. Romansky and his colleagues have reported in detail their method of prolonging the action of calcium penicillin by suspending it in a mixture of beeswax and peanut oil. At the request of the Office of the Surgeon General of the United States Army, Herrell and I undertook to evaluate this method of administration. We previously had studied the calcium salt of penicillin and had found it generally satisfactory for intravenous and intramuscular treatment of bacterial infections and no more irritating to tissues than the sodium salt. The suspension of calcium penicillin in beeswax-peanut oil mixtures was found to be a practical and effective method of delaying the absorption of penicillin after intramuscular and subcutaneous administration. A concentration of at least 0.03 of an Oxford unit of penicillin was maintained in the blood for twenty-four hours following a single intramuscular injection of 300,000 units of calcium penicillin in a 4.8 per cent mixture of beeswax and peanut oil. Previously the viscosity of the mixture made the administration of this preparation difficult. However, suitable amounts are now dispensed in individual syringes so that a single dose can be injected directly into the tissues. This greatly lessens the difficulty of administration. The incidence of troublesome local reactions and generalized allergic reactions from penicillin in beeswax-peanut oil mixtures has been higher in our experience than that reported by Romansky. However, these reactions have been transient. There has been no evidence of any permanent foreign body reaction. The absence of any serious irritating effects and the convenience of huge concentrated doses which need be given only at relatively long intervals are factors which emphasize the practicability of this method of administration. It seems highly probable that penicillin administered in beeswax-peanut oil mixtures will be of value in the treatment of syphilis.

Dr. George V. Kulchar, San Francisco: Drs. Romansky and Rein have given a satisfactory, safe, ambulatory, effective method for the treatment of syphilis. It seems that this method has certain advantages over the use of sodium penicillin in aqueous solution. For one thing, I believe that the effect of the penicillin, as pointed out, is prolonged over fourteen days on the average, or six days longer than the ordinary course of sodium penicillin. The second advantage is the ease of administration. The fact that it does not require hospitalization is a great economic advantage. It however appears that there are certain disadvantages to this method. One is the higher incidence of reactions, about which Dr. Nichols spoke. In his series at Stanford University, Dr. Barnett informs me that with use of sodium penicillin in 200 cases there have been no reactions. The patients have been carefully scrutinized, so that I doubt much if any kind of reactions have been missed. At the San Francisco City Clinic, calcium penicillin in peanut oil and beeswax has been used for the last ten months. Dr. Koch, the director of venereal disease, has supplied me with the data from that series. Among 126 patients, 98 of whom completed treatment, there were 9 who had severe urticarial reactions. There are, I believe, several possible explanations for this higher incidence of reactions. Possibly calcium penicillin may act as an antigen to a greater extent than sodium penicillin. It may be that either the beeswax or the peanut oil—we know that peanut oil is an antigen—may serve to sensitize the patient. The more logical explanation is that the sensitization develops over a period of, say, nine to ten days. With a residue remaining in the buttocks over that period, it is possible that this may lead to sensitization. It would be interesting if a statistical study were made as to the actual time of appearance of reactions. In the series from the San Francisco City Clinic mentioned, there were 98 patients who are available for statistical analysis. The system that was used there consisted of administration of 150,000 units of penicillin in beeswax and peanut oil twice a day over a period of ten days. Of the 98 who are available for analysis, 27 have been observed from five to ten months. There were no clinical relapses; there were 11 per cent failures, based on the serologic reactions, practically the same criteria being used as those used by Drs. Romansky and Rein. There were no local reactions of any consequence, but 3.3 per cent of the patients had to stop treatment because of urticarial reactions. It is possible that with the use of Benadryl or the newer Pyribenzamine (N'pyridil-N'benzyl-N-dimethylethylenediamine) these reactions may be controlled.

Dr. Thomas H. Sternberg, Los Angeles: I congratulate Dr. Romansky on this paper and on the amount of work he put into the development of calcium penicillin in beeswax-peanut oil. He has made a valuable contribution to the entire field of chemotherapy. Shortly after Dr. Romansky began the treatment of his present series of patients, the Surgeon General authorized two additional centers for the purpose of studying this method of therapy. The first was located at Fort Bragg, N. C., under the direction of Major William Leifer, and the second at Camp Howze, Texas, and later at Camp Livingston, La., under the direction of Major Franklyn Grauer. These centers began to operate early in 1945 but were closed shortly after V-J day because of the rapid loss of patients coincident to demobilization. A total of 200 patients with early syphilis were treated, the schedule consisting of a single injection of 300,000 units of calcium penicillin in beeswax-peanut oil daily for eight days, for a total dosage of 2,400,000 units. The Romansky formula was used. Thirty-five of these patients were lost from observation immediately. The rest were followed four to ten months, a period so inadequate that conclusions cannot be drawn. Nevertheless, in 97 of the group the serologic reaction for syphilis was negative at the time of the last examination. Included in this group of 97 patients were 50 with seronegative primary, 31 with seropositive primary and 16 with secondary syphilis. The status of 62 patients was considered problematic, since the reagin titer was declining but the serologic reaction was still positive. There were six frank serologic or clinical relapses. In the summary of these data, it appears that the results are comparable to those that might be expected for the same period of follow-up with use of 40,000 units of sodium penicillin every three hours for sixty doses, for a total of 2,400,000 units. Penicillin blood levels following a single injection of 300,000 units of the penicillin-beeswax-peanut oil preparation (Romansky formula) were performed at Fort Bragg, N. C., by Kirby and Rammelkamp. They were unable to demonstrate penicillin in the blood for more than twelve to eighteen hours in the majority of patients. For this reason it is believed that a more adequate dosage, such as 600,000 units daily, either as a single or as a split injection, should be used in the ambulatory treatment of early syphilis.

Dr. Marion B. Sulzberger, New York: I, too, want to express admiration for the work reported here. I second the opinions of those who said that the reactions produced by this preparation are higher in incidence and perhaps somewhat different in character from those produced by the injections of aqueous solutions of penicillin or of penicillin in oil. My associates and I have seen a number of cases of local reaction at and around the site of injection of the penicillin and beeswax and oil which took the form of swellings with considerable redness. Some of these looked as though they were going to be large sterile abscesses. However, though disagreeable and uncomfortable, these lesions did not break down. None of the reactions we saw produced any serious or lasting consequences to the patient, but they did interfere with the use of this preparation. I think that Dr. Romansky and co-workers have brought us another, and extremely important, application of a well known, established principle of chemotherapy. It is my conviction that this penicillin suspension contrasts in effects with the penicillin solution in the same way as suspensions of bismuth preparations in oil contrast with the soluble salts of bismuth. Again, the same principle is involved when one administers epinephrine in oil and gets the prolonged effects which are not possible when epinephrine is administered in aqueous solution. Again, the same principle is used when one makes suspensions of antigens or allergens in oil or other mediums and thus tremendously increases or potentiates their immunologic effects. Landsteiner and Chase and their co-workers and particularly

Jules Freund have shown that one can take poorly antigenic or allergenic substances, such as tuberculin, and by suspending them in oily emulsions—for example, suspending tubercle bacilli in oily emulsions—can produce specific tuberculin sensitivity in laboratory animals. No such regular production of tuberculin sensitivity was possible before without an actual infection with living bacilli. I think that, as Dr. Kulchar said, it is not astonishing but is rather to be expected that this oil-wax suspension of penicillin should potentiate the antigenicity or allergenicity of penicillin and thus tend to produce a higher incidence of allergic reactions. Both beeswax and peanut oil are unknown, not chemically defined, substances, or rather mixtures, and it is impossible to maintain their constancy. Beeswax is a variable mixture of a good many different things, and beeswaxes are of many different qualities. They contain extractives from different kinds of flowers and plants, according to where the bees feed. American beeswax sometimes contains sufficient ragweed allergen, sufficient "oleoresins" of ragweed, to give positive reactions to patch tests in ragweed-sensitive persons. Peanut oils are variable natural products or mixtures I don't think this is a serious criticism of this mixture of substances, but it is a consideration which should impel the search for other simpler substitutes which might have the same or even better effects.

DRS. ALFRED COHN, THEODORE ROSENTHAL and ISAAK GRUNSTEIN, New York: This report of favorable results in treatment of early syphilitic patients with calcium penicillin in beeswax and peanut oil may help to open the road for penicillin therapy of ambulatory patients with syphilis. Using a different oily vehicle—sodium penicillin in water in oil emulsion—the Venereal Disease Research Unit of the New York City Department of Health initiated a study on the treatment of early syphilis in March 1945, and it is still in progress and essentially in the experimental stage. However, the results obtained thus far justify a short discussion. A total of 35 male patients with early syphilitic infections received daily injections of penicillin in water in oil emulsions over a period of five days. The daily dose ranged from 400,000 to 1,000,000 Oxford units of penicillin administered intramuscularly at either twelve or twenty-four hour intervals. After total dosages of 2,000,000 to 5,000,000 Oxford units respectively, definite clinical regression of the syphilitic lesions was observed among all patients at the end of active therapy. Titrated Wassermann tests and flocculation tests (Kahn, Kline and Mazzini) were done on the serum of each patient before treatment and were repeated each time the patient reported for reexamination. As a rule the positive Wassermann reaction reversed to negative within a period of five to twenty-eight weeks. Of the 35 cases, 10 were followed for a varying period up to six months and 15 for a period of seven to twelve months, while 10 cases had no adequate follow-up. The only clinical relapse observed thus far occurred sixty days after treatment. This patient suffered from seropositive primary syphilis and was treated over a period of five days with a total dosage of 4,200,000 Oxford units of penicillin. Among the 15 patients remaining under observation for a period from seven to twelve months, none showed any signs of a clinical relapse. The serums of 2 patients yielded gradually decreasing positive reactions to the complement fixation and flocculation tests over a prolonged period of eight to ten months. In a third patient with secondary syphilis the serologic reaction reversed from negative to positive eight months after treatment. Intramuscular injections of penicillin in water in oil emulsion did not produce any serious local or systemic effects except transitory pains at the site of injection. Herxheimer reactions of a mild degree occurred in most cases. . . . These findings corroborate also the observations of Jawetz, who demonstrated in experiments on animals that the action of penicillin apparently persists after disappearance of the drug from the blood stream.

DR. G. W. BINKLEY, Cleveland: My associate, Dr. Johnson, and I had an experience with a reaction to penicillin in beeswax and peanut oil which indicates the need for a battery of three antigens in order to do allergenic tests in the presence of cutaneous reactions. The man received six daily injections of calcium penicillin in oil and beeswax. A combined urticarial and edematous dermatitis appeared about the tenth day. His reaction was controlled with Benadryl given orally. After the process had cleared up, tests were done both intradermally and epidermally with sodium penicillin (we were unable to obtain calcium penicillin at that time) with peanut oil and beeswax. There was no reaction to the sodium penicillin or to the beeswax. A 30 mm. flare with pseudopods appeared as a reaction to peanut oil. It was believed that in his case he could safely receive penicillin in some other vehicle.

DR. SAMUEL AYRES JR., Los Angeles: My experience with this substance is rather limited; however, I have heard lately that some delayed reactions related to paraffinomas have been observed. I wonder if Dr. Romansky will tell us whether he has observed or heard of any such delayed reactions. Of course, beeswax is not the same as paraffin, not a mineral substance and, therefore, is supposed to be absorbed. I wonder if experimentation on animals has been carried out to the extent of proving how completely the beeswax is absorbed, whether there is any residue and what the likelihood would be of foreign body reactions developing late, say maybe one or two years afterward, because the ease of administration and the other advantages of this type of therapy certainly lend a strong temptation to use this instead of the other method of administration.

DR. MONROE J. ROMANSKY, Washington, D. C.: As regards the incidence of reactions, an important point is whether the mixture is given intramuscularly or subcutaneously. We have given over fifty thousand injections of this material at Walter Reed General Hospital. Patients receive one or two injections a day, depending on what the condition may be. Penicillin in aqueous solution is not used. If the penicillin-oil-beeswax is given subcutaneously there is a greater incidence of local reactions, which, on the basis of the way they respond to treatment, appear to be of an allergic nature. If given intramuscularly, the incidence of allergic reactions is about 3 to 5 per cent. The reactions after subcutaneous administration have at times been treated incorrectly by the use of hot applications, which tend to aggravate. Cold applications or the usual antiallergic therapy, including use of Benadryl, will prevent and minimize these reactions. In patients receiving single daily injections of penicillin-oil-beeswax for about eight days, the allergic reactions tend to occur on the fourth to the twelfth day after the last injection, reaching their peak on the fourth day after initiation and tending to subside thereafter. Penicillin-oil-beeswax has been given for as many as one hundred and fifty consecutive days and been well tolerated by patients. When I first started this work the question of paraffinomas was uppermost in my mind, in view of the history of paraffin when given parenterally. In view of this, biopsy specimens of muscle have been obtained from hamsters, rabbits and human beings who have received the mixture. These biopsy specimens were obtained from one week to six months after the injections. Beeswax tends to disappear somewhere between the tenth and twentieth day by the action of the phagocytes. Paraffin is not removed by phagocytosis. In rabbits, at the end of two to three months only minute oil cysts with thin walls were found. These tended apparently over a period to collapse on the basis of muscle activity. In biopsy specimens taken from 2 patients who expired from other causes about two months after the last injection, all that could be found were two small, 1 to 2 mm., thin-walled oil cysts in 1 patient and a 10 mm. cyst in the other. There was no evidence of beeswax. As far as I know, in the treatment of about 2,000 patients there has been no evidence of a paraffinoma developing. In infants and children, after an injection of the mixture a nodule may be palpable for some time, but I believe that this is usually due to the material being given subcutaneously instead of intramuscularly. To return to Dr. Sulzberger's question on the use of liquid petrolatum, carbowax, aluminum jels and other substances, I originally tried almost all of them. None gave the prolonged blood level that is produced with penicillin-beeswax-peanut oil. It is extremely important that the penicillin blood levels should be those which are therapeutic against the organisms causing the disease which is being treated and that the presence of penicillin in the urine without a satisfactory level in the blood does not suffice.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 785)

(NOTE.—*Following is the fifth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 5. *The First Annual Session*

When President Nathaniel Chapman opened the proceedings of the first annual meeting of the American Medical Association in Baltimore on May 2, 1848 he used strong language in telling the profession of its responsibilities. In these days when organizations throughout the nation are attempting to create popularity for themselves by the practice of what has come to be called "public relations," we hear similar indictments. The words of Dr. Chapman published about a hundred years ago resound almost as if they were of yesterday. He said:

> "This assemblage presents a spectacle of moral grandeur delightful to contemplate. Few of the kind have I ever witnessed more imposing in its aspect, and certainly none inspired by purer motives or having views of a wider range of beneficence. The profession to which we belong, once venerated on account of its antiquity—its various and profound science—its elegant literature—its polite accomplishments—its virtues—has become corrupt and degenerate to the forfeiture of its social position and, with it, of the homage it formerly received spontaneously and universally. . . ."

Dr. Chapman then proceeded to tell the medical profession of his day what has been so frequently told to it in the years that have passed: that the medical profession always cleans its own house, that it does not need extraneous assistance in bringing about reform. Perhaps in anticipation of charges that might be made at some later date, he declined in advance to nomination for reelection to the presidency, saying "Rotation in office, I am persuaded, is the vital principle of every institution in this country. Especially do I consider it so in relation to our own association, national in its objects and constitution. Every section of the country is here represented, and equally engaged in a common cause. No monopoly of honor or privileges must be permitted to any one portion of it. I wish our conduct always to be dictated by liberality, justice and equality."

There were 195 delegates, and the Committee on Nominations was instructed to bring in the names of at least three nominees for each office. Moreover, it was required that the person elected should receive a clear majority of those voting.

The convention turned its attention to the sophistication and adulteration of drugs. Dr. A. H. Stevens of New York was elected President. Then came a number of extraordinary reports of the special committees which had been appointed in previous years. Early in the session Dr. J. C. Warren of Boston, who was first to operate on a patient under ether anesthesia in the Massachusetts General Hospital in 1847, addressed the meeting in reference to the preparation and value of chloric ether as a substitute for sulfuric ether and chloroform, whereupon Dr. F. H. Hamilton of Buffalo introduced a resolution "That, considering the present limited amount of authenticated facts in relation to the danger or safety of anesthetic agents in medicine, surgery and obstetrics, this association is not now prepared to determine upon their value or the propriety of their use, and that the subject be referred to a Special Committee who shall report at the next annual meeting." The resolution was referred to a committee and apparently not made the subject of any later report.

In addition to questions related to medical education and the publication of scientific papers, we find an interesting resolution asking the Committee on Hygiene to direct its attention to the following subjects: First, What is the influence likely to be produced by the extensive introduction of tea and coffee in the diet of persons under the age of puberty? Second, What is the influence of the substitution of the luxuries tea and coffee, as food, on the health of the laboring classes?

The reports of the committees occupy the rest of the volume of the Transactions of the American Medical Association for 1848. Volume I was printed for the Association by T. K. and P. G. Collins in Philadelphia. It contains some documents that are classic.

COMMITTEE ON MEDICAL SCIENCES

The Committee on Medical Sciences, under the chairmanship of W. T. Wragg of South Carolina, reported that it had examined all the journals published during the previous year, that there was too much literature, so that there was an embarrassment in choosing well rather than in collecting abundantly. They did not consider it desirable to limit themselves merely to contributions from America but had collected from all over the world. They then presented some fifty pages of abstracts from the medical literature of the day, dealing with a great variety of subjects.

COMMITTEE ON PRACTICAL MEDICINE

The Committee on Practical Medicine had been charged to report on the more important improvements effected in this country in the management of individual diseases and to report on the progress of epidemics. This committee also had examined the medical periodicals of the day and concluded quite wisely that great discoveries are not really made in any one year. It singled out for special notice a procedure developed by Dr. Gurdon Buck of the New York Hospital which was the multiple scarification of the walls of the throat in the presence of edematous swelling or what was then called "oedematous laryngitis" in its suffocative stage. This, no doubt, was the condition from which George

Washington died and would be called today either "septic sore throat" or "diphtheria."

Then came a rather prolix discussion of epidemics, with special attention to the frightful condition of emigrants coming from Europe, contrasting particularly the nutrition, cleanliness and general hygiene of the German emigrants with that of the Irish, who arrived "in most cases enfeebled from the want of sustenance, and on shipboard, destitute of supplies of wholesome food, depressed of mind, clothed in filthy garments and crowded and confined in air rendered pestiferous by the excrementitious matters eliminated from their own bodies." It called attention to the fact that thousands had perished on the voyages to the United States and Canada. From one ship, the *Virginia,* bound from Liverpool to Quebec, with 470 passengers, 158 were buried at sea.

During the year 1847, 100,000 souls left the British Isles for Canada. More than 5,000 of these died en route and another 8,000 within a few weeks after their arrival. The disease from which these people perished was typhus in its genuine form, and in some ships smallpox, dysentery and measles swelled the amount of mortality. There was much discussion of the ability to distinguish between typhus fever and typhoid fever.

As a supplement to its report the committee included the complete statement of Gurdon Buck on "Oedematous Laryngitis" together with pictures in color of the condition concerned and of the instruments especially designed by him for performing his operation.

THE COMMITTEE ON SURGERY

The Committee on Surgery was supposed to prepare a report on all the important improvements in the management of surgical diseases in America during the year, to which it succinctly replied "Neither brilliant discoveries nor any extraordinary improvements in surgery marked the past year." The committee, nevertheless, decided to make a report of progress, and the major portion of its report deals with cutting for stone and the surgical treatment of aneurysms. Dr. Daniel Brainard of Chicago had found iodine useful as a substance to be injected into infected wounds.

Then comes the report on anesthesia. Eighteen months had elapsed since the introduction of ether by Morton. A large and intelligent body of the medical community, including some of the most eminent surgeons, considered the question settled. They considered the dangers of etherization so inconsiderable as to justify its use prior to all surgical operations. Another class of surgeons wished to limit the use of anesthetics to severe operations and to discourage their general employment. A small portion of the profession objected altogether to the use of anesthetics as dangerous and harmful in their tendency.

The committee refused to take a definite stand. It did, however, offer the opinion of Dr. Henry J. Bigelow of Boston, and it took pride in the fact that anesthesia was an American contribution. At the same time the committee noted with regret that the early history of the discovery "is encumbered with angry disputes amongst rival claimants for the honor, and that attempts were made by those most intimately interested in the claim. . . ." Much consideration is given to the claims of Horace Wells, but it is stated clearly that Wells abandoned his experiments begun in 1844, and that the first successful experiment was performed by William T. G. Morton, a dentist of Boston, on a patient from whom he extracted a tooth on Sept. 30, 1846. Dr. Henry J. Bigelow had read a paper in Boston on Nov. 3, 1846. It was published in the *Boston Medical and Surgical Journal* November 18. Within six weeks of the publication of that paper, ether had been tested and was being warmly advocated among surgeons in London. The report then lists all the various surgeons in the United States who had already used ether in surgical operations and it was noted that fatal effects following the use of chloroform had been more frequent than from ether.

Incidentally the committee reported also that it had received a number of letters about the curability of cancer and the results of operations on this class of tumors, but apparently this was too much for the committee and it made no report but merely submitted the letters to the convention.

COMMITTEE ON OBSTETRICS

The Committee on Obstetrics had the duty of preparing a report on all the important improvements in obstetric art and of the management of diseases peculiar to women and children. Obviously the matter of chief concern was the use of the anesthetics in childbirth. The committee got itself into the usual argument that labor is a physiologic or natural process and that pain should therefore be endured, but the committee attached little importance to this objection. It wisely decided that if one adopted that point of view it would be impossible even to give remedies to the parturient woman. Already anesthetic agents had been used in 2,000 cases and, as far as the committee was able to learn, without a single fatal result and few, if any, untoward results.

The committee also suggested that doctors try out chloroform on themselves as a means of dispelling their vague apprehensions in relationship to it. Indeed the committee recommended that the doctor begin with 20 to 30 drops and gradually increase the quantity to find out how to use the chloroform safely and to acquire tact and confidence in giving it to others.

There was much discussion of the relative advantages of ether and chloroform for different types of cases, chloroform being considered more convenient and ether safer, but both efficient.

To this report were appended half a dozen communications from practitioners who had used anesthetics in labor.

COMMITTEE ON MEDICAL EDUCATION

The Committee on Medical Education was charged with preparing a report on the general condition of medical education in the United States in comparison with medical education in other enlightened nations and to note particularly the quality of instruction, the number of pupils and the requirements in various states.

The committee pointed out that in most foreign countries the standard of qualifications necessary for a doctorate in medicine was higher than in the United States and that the preliminary education was broader and more thorough. As a result of the previous meeting of the American Medical Association, some medical schools had already lengthened their curriculums and added other courses of instruction. Incidentally, the committee noted that in Harvard University candidates who had not received a college education were subjected to an examination on natural philosophy and the Latin language and were required to translate *ad aperturam libri* Cicero's orations. The same practice was followed in the medical societies of Massachusetts in their examinations for licenses to practice.

The committee had already decided that there were too many doctors in the United States, the proportion being five times as great as in France. It was urged that private teachers exercise greater circumspection of students taken into their offices. The committee felt that the oversupply of doctors was largely responsible for the rise of quackery and charlatanism, and it urged that a proper medical education could be had only by spending a certain amount of time in a hospital in the actual care of patients.

COMMITTEE ON MEDICAL LITERATURE

Looking back on the perspective of one hundred years, the report of the Committee on Medical Literature, under the chairmanship of Oliver Wendell Holmes and including such distinguished men as Enoch Hale, G. C. Shattuck Jr., Daniel Drake, John Bell, Austin Flint and W. Selden, merits first place. There are some sections so clearly of the style and manner of thought of Oliver Wendell Holmes that they merit frequent quotation. There is an adequate record of the history of medical publications in the United States, with complete reports of existing medical journals.

A typical medical journal of the time is thus described:

> The first part of each number is devoted to original articles, consisting of essays, histories of epidemics and endemics, series of cases and single cases, and accounts of operations. Occasionally a more detailed and comprehensive history of some disease is introduced under the name of *monograph,* and not unfrequently extensive statistical tables are given, bearing especially upon surgical and obstetrical practice. Then follow *Reviews* or formal examinations of works recently published, usually analytical in character and having for their principal object the book rather than the general subject of which it treats. To this division succeeds a miscellaneous and heterogeneous assemblage of *bibliographical notices;* the sweepings of the critical *atelier;* the rinsings and heeltaps of the critical banquet; a necessary part of the editor's prospectus, but one which is least gratifying to minute inspection. Here the importunate friend receives his expected compliment, the dull dignitary is pacified with his scanty morsel of eulogy, the Maecenas is paid in fair words for his patronage; the book which must be noticed and has not been read is embalmed in safe epithets and inurned in accommodating generalities. Lastly, a considerable part of the number is made up of selections, either taken promiscuously from other journals and recently published works, or, in the better managed periodicals, classified so as to present a summary of the recent progress of science in its several departments.

The committee found that a great proportion of a medical journal was made up of quotations from other medical journals, so that all the medical journals were a good deal alike, since there were very few original articles published of any merit and they were found again and again repeated in the medical journals.

Following the discussions of the periodicals come discussions of the books in each of the important medical subjects and then in some half dozen pages a witty analysis of medical writings, classic in its diction and in its consideration. Special attention was paid to the so-called introductory lectures, which are really the opening statements delivered by the deans or professors in the medical schools to the incoming students. Says the report:

> They must not be judged too harshly, for they are delivered to young men, who like high seasoning, and they naturally partake somewhat of the character of advertisements. Many of them are agreeable and appropriate performances, but others are open to severe comment. Turgid and extravagant attempts at eloquence, a fondness for effete Latin quotations, a parade of scholastic terms where simple ones only are called for, an inclination to adopt the cant phrases of political and literary writers, are the common faults of these productions. The physician should remember, that his style has no more occasion for pomp of oratory and glitter of epithet, than his costume for the gold lace and feathers which belong to the military chieftain. Nothing is more offensive than an attempt to tell that which should be said plainly and decently, in high flown language. It vitiates the taste of the student who listens to it or reads it, and exposes the profession to derision from those who cannot value the important truths disguised by such ill chosen finery.

COMMITTEE ON PUBLICATION

The Committee on Publication, headed by Isaac Hays, reported that it had printed 2,500 copies of the Conventions of 1846 and 1847 and they still had 800 copies left.

There is a complete list of the members who paid $3 each for membership in the Association. Then come a number of communications dealing with the ethics of the pharmaceutical profession and an exposé of the adulteration and falsification of drugs sold in the United States.

The committee, which had been supposed to ascertain the total number of doctors in the United States, reported for the states of Virginia, Delaware and Massachusetts. And finally there were two scientific papers and lists of the officers and members of the American Medical Association.

A good index completed what is even for these times an extraordinarily interesting volume.

(To be continued)

Clinical Notes, Suggestions and New Instruments

HAY FEVER AND ASTHMA FOLLOWING MAXIMUM EXPOSURE TO RAGWEED

FRANK L. ROSEN, M.D.
Newark, N. J.

According to Durham,[1] the highest ragweed pollen count in the United States has been recorded near Indianapolis. Clinical corroboration of this observation was afforded me when I was stationed for the ragweed seasons of 1944 and 1945 at Wakeman General Hospital, Camp Atterbury, Ind., some 35 miles south of Indianapolis.

The following case report is illustrative of many of a similar nature which will plague the Disability Rating Boards of the Veterans Administration for many years, requiring solomonic wisdom for fair adjudication both for the veteran and the government.

REPORT OF CASE

A white soldier aged 21 was admitted on Aug. 26, 1944 to the allergy ward of Wakeman General Hospital, Camp Atterbury, Ind. He had been affected by severe sneezing, stuffed nose, redness and watering of the eyes for the past week. There was no previous history, personal or familial, of hay fever, asthma or other allergic manifestations. However, the patient admitted he could have had mild sneezing in the summer or autumn without distinctly recollecting it. This was his first summer in the middle west; previously he had always resided in Newark, N. J.

Physical examination on admission revealed that the patient had severe symptoms of hay fever with a pale, boggy, intensely swollen nasal mucosa, injected conjunctivas and a right otitis media, nonsuppurative. Intracutaneous ragweed tests were decidedly positive. Serologic tests and urinalysis were normal. The blood count was normal except for a 10 per cent eosinophilia.

---

[1] Durham, O. C.: The Pollen Count of the Air in North America, J. Allergy 6: 128 (March) 1935.

Acute symptoms of hay fever persisted for about two weeks, than subsided gradually. No relief was afforded by ephedrine nose drops or ephedrine-phenobarbital capsules. The patient was reclassified for limited service, than returned to duty on Sept. 27, 1944.

He did well until Oct. 23, 1944, when he was readmitted to the allergy ward. This was well past the end of the ragweed season for that area. He had been wheezing for the past few hours. Nasal and ocular symptoms were absent, and this was the first asthma attack he had ever experienced.

Physical examination revealed a patient with moderate asthma; the lungs showed asthmatic rales and breath sounds throughout. The ear, nose and throat consultant reported that the nose showed swelling of the turbinates, especially the right, bathed in watery secretions. Purulent secretion or polyps were not observed. The frontal sinuses transilluminated clear, the antrums fair.

Laboratory procedure disclosed the following: A roentgenogram of the chest revealed normal conditions. A roentgenogram of the sinuses revealed a circumscribed, rounded density arising from the floor of the right maxillary antrum, and another from the medial wall, representing a polyp formation or mucocele. Only a small amount of aeration was visualized in the upper portion of the antrum. There was thickening of the lining membrane of the ethmoidal cells on the right side. The remainder of the paranasal sinuses showed normal aeration throughout. Urinalysis and serologic tests were normal. The blood count was normal except for an 11 per cent eosinophilia. Thirty-six intracutaneous dermal tests with common inhalants, contactants, epidermals and foods were negative except for buckwheat, which was decidedly positive; orange, moderately positive, and ragweed, slightly positive. (Ragweed was definitely positive during the ragweed season.)

The patient was placed on a diet without buckwheat and citrus fruits, and ephedrine sulfate-phenobarbital capsules and saturated solution of potassium iodide were administered three times a day. Moderately severe asthma which required epinephrine injections at least once a day persisted for about ten days. The attacks tapered off, averaging about one a week for the next six weeks. A repetition of the blood smear at this time disclosed an eosinophilia of 8 per cent. Examination of the nose revealed slightly pale and boggy nasal mucosa, though nasal and paranasal symptoms had not been observed for the past two months. A follow-up roentgenogram of the sinuses showed moderate clouding toward the floor of the right antrum caused by membranous infiltration or congestion; the sinuses were otherwise normal. On Jan. 8, 1945, after a three week symptom-free period, the patient was given a medical discharge from the Army because of bronchial asthma.

The patient was next seen, after he and I had both become civilians, in my office in Newark, N. J., on May 13, 1946 (sixteen months later). He had been perfectly well until one month previous, when he had begun to observe difficulty in breathing at night. There had not been any nasal or paranasal symptoms or other manifestations of allergy. He had been on a normal diet.

Examination revealed a well developed man who appeared to be breathing normally. The lungs showed a slight prolongation of the expiratory phase of respiration throughout, with no rales. The nasal mucosa was slightly pale and boggy. Intracutaneous allergy tests gave slight positive reactions to dust, mixed trees, timothy and ragweed.

COMMENT

In all probability this patient will now require prolonged allergic management. The problem arises as to whether he and others like him are entitled to medical care from the Veterans Administration and to disability ratings if the asthma is of sufficient frequency and intensity. The Veterans Administration, in many cases, reasons that the person is potentially allergic because of hereditary factors. The allergic chain of symptoms could certainly have developed whether or not the patient was in the armed forces. On the other hand, the ragweed-sensitive patient who is stationed in an area of dense ragweed pollination may suffer accentuation of various allergic symptoms for many years. The patient states, and in my opinion justly, that if he was not in the Army he would never have moved to such an area. The problem is extremely complex, and there are as many different decisions as there are Veterans Rating Boards. To insure fairness to all concerned, decisions in cases of this type should be made by trained allergists.

SUMMARY

A case of hay fever followed by asthma occurred after maximum exposure to ragweed pollen in a soldier who had previously lived in an area with a much lower ragweed pollen content. Previously he had not had hay fever or other allergic clinical symptoms. The problem of medical care and compensation for veterans in cases of this type is one which will face the Disability Rating Boards of the Veterans Administration for many years.

33 Johnson Avenue.

Council on Foods and Nutrition

The question of the essentiality of fatty acids in human nutrition is discussed in this article. It was prepared by the authors at the request of the Council and has been authorized for publication.

JAMES R. WILSON, M.D., *Secretary.*

ESSENTIAL FATTY ACIDS AND HUMAN NUTRITION

ARILD E. HANSEN, M.D., Ph.D.
Galveston, Texas
and
GEORGE O. BURR, Ph.D.
Minneapolis

Interest with regard to the significance of fat in the diet was evidenced even by early investigators in the field of nutrition, and these workers were led to believe that the only role of dietary fat was to serve as a rich source of calories. Later observers, however, emphasized its additional importance as a source and as a vehicle for the absorption of certain vitamins. In 1929 the Burrs[1] discovered the essential nature of certain fatty acids in the nutrition of the rat. For the first time, then, a specific function could be attributed to fat other than its energy producing property and its action as a vitamin carrier. It must be emphasized that the observation proving linoleic acid and arachidonic acid to be dietary essentials was not made until young laboratory animals had been maintained on diets extremely low in fat for relatively long periods of time. The likelihood that a human infant would subsist for a prolonged period on a diet practically devoid of fat, yet complete as regards other known dietary essentials, is practically nil. Hence the recognition in infants and children of any characteristic clinical picture or type of malnutrition which may result from the specific lack of certain fatty acids in the diet has not been demonstrated conclusively.

In this presentation, in addition to a consideration of the experimental results which have been observed with laboratory animals on low fat diets, as well as the effect of the administration of certain fatty acids to these animals, an attempt will be made to summarize the data which have a bearing on the possible importance of the essential fatty acids in human nutrition.

From the Department of Pediatrics, University of Texas School of Medicine (Dr. Hansen), and the Division of Physiological Chemistry, University of Minnesota School of Medicine (Dr. Burr).

[1] Burr, G. O., and Burr, M. M.: A New Deficiency Disease Produced by the Rigid Exclusion of Fat from the Diet, J. Biol. Chem. **82**: 345, 1929; On the Nature and Role of the Fatty Acids Essential in Nutrition, ibid. **86**: 587, 1930. Burr, G. O.; Burr, M. M., and Miller, E. S.: On the Fatty Acids Essential in Nutrition, ibid. **97**: 1, 1932.

It is quite evident that the method of approach for establishing the human need for these fatty acids cannot be the same as that used for experimental animals. Furthermore, the fact that adequate direct methods for determining the amount of linoleic and arachidonic acids in blood serum and animal tissue have not been available has been an additional handicap in the prosecution of studies with human subjects. Consequently, much of the evidence we have for the human need for the essential fatty acids is indirect.

ESSENTIAL NATURE OF FATTY ACIDS IN ANIMAL NUTRITION

The term "essential fatty acid" was introduced in 1930 and since that time has been used to designate a group of unsaturated fatty acids which will stimulate renewed growth of rats after they have reached a plateau on a low fat diet. Careful exclusion of the essential fatty acids from the diet in rats leads to (1) development of scaly skin and caudal necrosis, (2) decided retardation of growth, (3) increased water consumption and (4) early death. Any or all of these signs may be used for a quantitative assay of the needs for essential fatty acids. Other more or less specific effects of the deficiency are histologic changes in the ovaries, uterus and other tissues; poor ovulation, reproduction and lactation in the female, male sterility, high respiratory quotients and high metabolic rates, kidney lesions and hematuria. The scaly skin in rats, which is very striking in a dry climate, may be suppressed by high humidity. The time of appearance of the first definite symptom (scaly skin) depends largely on the amount of unsaturated acids stored in the body fat of the young. Hence any animal which has had access to a high fat diet before the experiment is started will maintain its normal appearance for a long time because of the low rate of metabolic use of stored essential fatty acids.

TABLE 1.—*Purified Fatty Acids Tested for Activity in Curing Fat Deficiency in Small Animals*

Positive Response	Negative Response
Linoleic	All saturated acids
Linoleyl alcohol	Oleic
Linolenic	Elaidic
Arachidonic	12 Oleic
Docosahexenoic *	Erucic (13 docosenoic)
Hexahydroxystearic	Ricinoleic (12 hydroxyoleic)
	Linolelaidic
	9,11-Linoleic
	α Eleostearic (9,11,13-linolenic)
	Dioxidostearic
	Trihydroxystearic
	Tetrahydroxystearic
	Chaulmoogric
	Clupanodonic † (Octa decatetrenoic)

* Not purified by crystallization but by fractional distillation of the ester.
† This preparation was found to be toxic

In table 1 are listed[2] the purified fatty acids that have been tested for their activity in curing a fat deficiency in small animals. Some of these acids have been used only once in a few animals. Linoleic, linolenic and arachidonic acid have been studied most extensively. Linolenic acid and the higher acids of fish oil bring about renewed growth in rats without curing the skin. Only linoleic acid and arachidonic acid give complete cures, but, strictly speaking, only one of these is essential. If either linoleic or arachidonic acid is added to the diet, a complete cure of the deficiency symptoms will take place. However, since linoleic acid is of plant origin and arachidonic is of animal origin, the former should be considered the primary dietary essential.

The rate of use of these unsaturated fatty acids determines the level of requirement. It has been found that prophylactic daily doses of about 20 to 25 mg. of linoleic acid promote good growth and reproduction in rats, but for optimum lactation 100 mg. is recommended. In curative experiments 50 to 100 mg. daily appears to be distinctly superior to lower doses. Assuming that the minimum adequate daily intake of linoleic acid is 100 mg. for a rat consuming 10 Gm. of diet, the linoleic acid requirement can be set at about 1 per cent of the diet. Since it has not yet been possible to establish the requirement for man through direct experimentation, a corresponding level of intake (1 per cent of the diet) has been recommended in human nutrition on the assumption that human beings and rats have the same metabolic requirement for this food factor.

By far, most of the work on the essential fatty acids has been done on the rat as an experimental animal. However, Hansen and Wiese[3] found in maintaining young dogs on a low fat diet that the most striking observation with these animals was the development of dryness of the hair and skin and flaky desquamation of the skin. Addition of fresh lard to the diet resulted both in preventing the appearance of these conditions and in restoring the abnormal skin to a normal state. A fat deficiency syndrome characterized by disturbance in growth, a dandruff-like dermatitis and early death also has been produced in mice.[4] These symptoms were cured by the addition of lard to the diet.

STUDIES BEARING ON RELATION OF UNSATURATED FATTY ACIDS IN HUMAN SUBJECTS

Experimental Use of Diets Very Low in Fat.—Clinical Observations: Comparatively few studies with human subjects have been carried out in which the effect of diets extremely low in fat has been observed for an extended period of time. Von Gröer[5] in 1919, prompted by Aron's study with rats on low fat diets, maintained 2 infants on a diet of skim milk for a period of nine months. He observed that both infants showed poor growth but attributed this to a respiratory tract infection from which both infants suffered severely and for a much longer time than other infants who were similarly affected in the hospital ward. One of the children on the low fat diet developed evidence of exudative diathesis, and the diet was discontinued because of the lack of appetite. Holt and his co-workers[6] in 1935 kept 3 infants aged 4 to 6½ months on a diet containing about 1 Gm. of fat per day for two to seven days. One of these infants, they noted, developed spasmodic bronchitis and an eczematous eruption, which cleared when fat was restored to the diet and recurred when fat was again eliminated. Apparently the authors did not consider this phenomenon a mere coincidence. In 1937 Chwalibogowski[7] reported having maintained 2 infants from birth to

Experimentaluntersuchungen über kalorisch Ernährung des Säuglings, Acta pædiat.

13 and 15 months of age on a diet consisting of skim milk, sugar and cereal. Later, fruit compote and carrots were added to the diet, and both children were given ultraviolet radiation at various intervals. Although no skin manifestations are described by the author for either child, both were found to be anemic when 11 to 12 months old and both suffered from repeated infections. During the fifteen months observation, 1 child had two attacks of grip, 2 of sore throat and 1 of pyuria. The other child had sore throat, grip and measles. The low fat diet in the latter instance was discontinued at the end of thirteen months because of lack of appetite. During none of these observations were any attempts made to determine the kind or amount of fat synthesized by the body.

Hansen and his co-workers have had the opportunity to observe the effect of a practically fat free diet on 4 human subjects. Preliminary observations were made with 2 normal infants for a period of ten weeks. Both infants suffered from attacks of impetigo and prickly heat which were resistant to the usual forms of treatment. Brown, Hansen, Burr and McQuarrie[8] in 1938 reported studies on an adult subject who was observed for a period of six months while on a low fat diet. When this same diet was fed to young rats, they developed the typical fat deficiency syndrome. Subjectively, in the adult under observation the most striking effect was the absence of the sensation of fatigue and a decrease in the migraine-like headaches from which he had suffered periodically. The respiratory quotient showed a slight increase, which response was similar to that noted in rats. The fourth instance[9] in which an extremely low fat diet was used for a prolonged period in a young human subject was that of a child with chylous ascites. The diagnosis was made when the child was about 3 weeks of age, at which time about a liter of creamy fluid was removed from the peritoneal cavity. Because the absorbed fat could not enter the blood stream, it was believed that placing the child on a low fat diet might decrease the fluid accumulation in the abdominal cavity. At first the diet consisted of concentrated skim milk and the usual vitamin supplements, but later vegetables and cereals were added. He was maintained on this type of regimen until he was 23 months of age. Although growth and development of the patient were fairly satisfactory, he never had the appearance of a robust child. He acquired a number of respiratory infections, and it appeared to the staff physicians that he reacted to these more severely than is normally expected. The most striking clinical finding, however, was with reference to the skin. The child became afflicted with impetigo on two occasions, and these infections were much more difficult to clear up than those encountered in the other infants in the same ward who were similarly affected. During his first summer, at the age of about 8 months, he developed a prickly heat eruption, which dermatitis persisted for months into the cooler weather, long after other infants in the same ward having the same type of rash had recovered. During the last half of the first year he developed eczematous patches on his body and face at various times, but these responded quite well to treatment with crude coal tar ointment.

In summary, on the basis of the work of various authors regarding clinical observations with human subjects maintained on diets very low in fat, it is apparent that no specific clinical syndrome develops during a period of one to two years. It may be pointed out, however, that the duration of sustenance on this type of diet in the patients studied thus far is short compared with the length of time that is necessary to produce distinct symptoms in experimental animals. Even in the diet of the experimental animal evidence of lack of fat in the diet requires a relatively long time to develop. For example, in the rat symptoms and signs do not develop until about one-half of the time from birth to maturity. Likewise in the dog the interval for the development of dermatologic signs is almost as long, relatively. Human infants maintained on low fat diets even for the periods mentioned are only one-sixth to one-eighth of the period from birth to maturity, or, comparatively speaking, one-third of the time required to develop a deficiency in experimental animals.

Serum Lipid Studies in Patients on a Low Fat Diet: Early observations of Hansen and Burr[10] showed that the serum lipids of rats suffering from the fat deficiency syndrome had lower iodine numbers than those of control animals. Likewise, in the preliminary studies of Hansen with the 2 infants on a low fat diet a similar decrease from the normal was noted in the iodine value of the blood fat. Periodic determination of the serum lipids in the patient with chylous ascites revealed the iodine values of the total fatty acids to be definitely lower than those of normal infants. The degree of unsaturation of the fat in both the acetone insoluble (phospholipid) and acetone soluble (glyceride + cholesterol ester) fractions was abnormally low. On one occasion it was possible to separate the triglyceride fatty acids from the cholesterol ester fatty acids, and in this instance it was found that the iodine numbers of the fatty acids in both portions were low. Studies by Wiese and Hansen[11] with dogs on low fat diets revealed that the greatest drop in the iodine number appears in the cholesterol ester fatty acids. Normally the cholesterol ester fatty acids are the most highly unsaturated of the fatty acids in the blood serum. The iodine number of the total fatty acids in the adult subject was also found to be decreased while on the low fat diet. It was possible to brominate the fatty acids in the serum in this case, and the findings with regard to the linoleic and arachidonic acids expressed as percentages of the total fatty acids are given in table 2.

TABLE 2.—*Linoleic and Arachidonic Acids Expressed as Percentages of Total Fatty Acids*

	Arachidonic Acid	Linoleic Acid
Normal diet	3.2	5.7
Low fat diet (for six months)	1.87	3.2

In all the serum lipid studies of the subjects on low fat diets it was found that the total amount of fatty acids in the various fractions has been within normal limits. It appears from these data that the animal organism is able to synthesize sufficient fat to maintain a normal level of blood lipid but apparently is unable to synthesize certain highly unsaturated fatty acids.

Relatively Low Fat Intake Because of Faulty Absorption.—Well controlled experiments which attempt to determine the effect of the lack of dietary fat on human subjects are relatively meager; however, there are important clinical conditions in which a defect in fat absorption is present. In patients with steatorrhea not only is there faulty absorption of fat, but, in addition, these patients often are advised to use low fat diets and there results a situation which is equivalent to maintenance on a diet quite low in fat. This condition usually exists for a prolonged period. It has long been known that patients having difficulty with absorption of fat may develop a deficiency state of one type or another. However, it has never been fully ascertained whether or not the malnutrition which is seen in patients with idiopathic steatorrhea or the celiac syndrome may be due in part to the specific lack of certain fatty acids. A clinical observation which is often made in some cases of a prolonged steatorrhea is the presence of dermatologic abnormalities. This observation may be of some importance in view of the fact that in experimental animals one of the chief manifestations of a fat deficiency is the development of an abnormality of the skin. In 1932 Bennett, Hunter and Vaughan [12] reported the presence of skin eruptions in 7 cases of idiopathic steatorrhea. These authors state that "The frequent occurrence of skin lesions appears too striking to be mere coincidence." Konstam and Gordon [13] also confirm this observation and report pruriginous vesicular dermatitis in a man aged 55 with steatorrhea. Riley [14] reports the finding of "large circumscribed erythematous areas" in a boy aged 17 years with idiopathic steatorrhea. In a 1944 report by Luzzatti and Hansen [15] on 10 infants and children in whom the diagnosis of celiac syndrome was made, 3 of the patients showed evidence of macular rash or eczematous lesions. Further evidence that some of the above patients possibly may actually suffer from the lack of specific fat is suggested by blood lipid studies. The authors found that the iodine number of the fatty acids in patients with the celiac syndrome was exceptionally low, 70 to 86, compared with the normal range of 98 to 113 for their control subjects in the same age group. The amount of fatty acid in the various fractions of the blood lipids was essentially normal, but the degree of unsaturation was abnormally low in all fractions. This indicates again that these patients can synthesize saturated fatty acids from sources other than dietary fat but are unable to synthesize unsaturated fatty acids to a sufficient extent to maintain the normal degree of unsaturation of the blood lipids. The establishment of a normal range for the iodine number of the serum fatty acids in human subjects and the possible nutritional significance of maintaining this degree of unsaturation in the blood is further suggested by the clinical findings and blood lipid analyses in patients with eczema.

Study of Patients with Eczema [15a]—It was first reported in 1933 by Hansen [16] that some infants with eczema appeared to be definitely benefited clinically when fats containing the essential fatty acids were added to the diet. This observation led to a study of the blood lipids of eczematous and normal noneczematous infants and children. It has been found by Hansen and his co-workers and also by Finnerud, Kesler and Wiese [17] using some 150 noneczematous control subjects and 180 eczematous patients that while there is no significant difference in the total amount of fat in the serums of the two groups of individuals the relative degree of unsaturation of the serum fatty acids in the patients with eczema is definitely less than in that of control subjects. The serum fatty acids of 82 per cent of infants under 2 years, 74 per cent of children from 2 to 15 years and 55 per cent of older subjects show iodine numbers *below the normal range of 95 to 130.* These findings have been confirmed by Faber and Roberts [18] as well as by Schornstein.[19] On the other hand, Ginsberg, Bernstein and Iob [20] found no difference between the iodine number of the serum fatty acids for patients with infantile eczema and those for normal subjects.

Pooled samples of lipid extracts of the serum were studied by Brown and Hansen [21] wherein it was found that the content of arachidonic and linoleic acid was less in the patients with eczema than in the pooled samples of the lipid extract of control subjects. These acids were determined as polybromides and tetrabromides and the values as percentage of the total fatty acids in the serums are summarized in table 3.

It has been found further by Hansen,[16] by Cornbleet and Pace,[22] by Finnerud, Kesler and Wiese [17] and by Ginsberg, Bernstein and Iob [20] that the addition of fats rich in linoleic and arachidonic acid such as fresh lard, corn oil and raw linseed oil to the diet of eczematous patients has resulted in a definite amelioration of the skin eruption in a considerable portion of the patients and in a complete clearing of the skin in some instances. In most of the patients studied by Hansen and by Finnerud and his co-workers the skin eruptions were resistant to the usual forms of therapy, yet more than 50 per cent of these patients have shown great improvement. The clinical response to the addition of one of these fats to the diet has been most evident in those cases in which the iodine number of the blood fat has been below the normal range. Improvement in the condition of the skin has usually been accompanied by a rise in the iodine number of the serum fatty acids to a normal level. Whether or not these responses in the condition of the skin of eczematous patients to the ingestion of fat containing the essential fatty acids accompanied by a rise in the iodine number of the serum fatty acids is a result of supplying

a deficiency of these fatty acids is not definitely established, but the evidence seems to indicate that there may be either a very low intake or an abnormally high requirement of these patients for unsaturated fatty acids which are not synthesized by the body. Epstein and Glick[23] and also Taub and Zakon[24] found no beneficial effects which could be attributed to the ingestion of linseed oil.

It has been observed by a number of clinicians that infantile eczema is less prevalent in breast fed infants than in partially breast fed or artificially fed infants. Grulee and Sanford[25] in a five year study of 20,061 babies found eczema to occur seven times more frequently in artificially fed than in breast fed infants. Robinson[26] also noted skin rashes to be less common in breast fed infants than in infants receiving various formulas containing evaporated milk. In this connection it is interesting to note that Hilditch and Meara[27] in 1944 reported higher percentages of linoleic and unsaturated C_{20-22} acids in human milk fat than in cow's milk fat. Preliminary studies undertaken in 1935 by W. R. Brown and the authors to determine the arachidonic and linoleic acid content of breast milk of mothers nursing eczematous infants showed that the values for these fatty acids tended to be somewhat lower than those for the breast milk of mothers nursing infants with no skin eruption.

COMMENT

In regard to clinical observations made thus far with human subjects, there is no evidence to indicate that a lack of the essential fatty acids produces a disturbance in growth, hematuria, kidney lesions, impaired reproduction, lactation or sterility, which abnormalities are attributed to the dietary lack of either linoleic or arachidonic acid in small experimental animals. However, as one of the most characteristic findings in all animal studies is an alteration in the appearance and character of the skin, it is perhaps not surprising to find a possible relationship between dietary fat and the skin in some human subjects.

The evidence from studies with human subjects on low fat diets for periods up to two years is not very striking in regard to the possible development of an abnormality of the skin. However, the child with chylous ascites who was maintained for the longest time on a low fat diet did develop some eczematous-like lesions and did have more difficulty than expected with both impetigo and prickly heat. This would be in line with observations of Hansen and Wiese[28] with dogs wherein it was found that the skin of animals on a fat free diet appeared to be less resistant to impetiginous infections than animals receiving fresh lard in the diet. That the unsaturated fatty acids may be concerned with the natural integrity of the skin in the healthy state is suggested further by the observation of patients with chronic eczema. The true therapeutic significance, limitations and indications for the addition of substances such as fresh lard or vegetable oils to the diet of these subjects has not been completely evaluated. However, the overall experience of Hansen with approximately 120 patients, all of whom were suffering from an intractable form of eczema and all of whom received supplements of a fat or oil rich in the essential fatty acids, indicates that this type of therapy may be a useful adjunct in this condition. Of the patients who have been studied long enough to interpret the results, in about one half the improvement in the condition of the skin has been excellent, in one fourth the improvement has been definite and in the remaining fourth there has been little or no change observed. No relationship between unsaturated fatty acids and allergy has been demonstrated.

Although the specific function of the essential fatty acids in maintaining a healthy skin, if such a function exists, is not known, their importance in this respect is further evidenced by the work of Hansen, Wiese, Kooda and Fredericks[29] with dogs. These authors found that the skin of young dogs receiving fresh lard in the diet was definitely more resistant to the effect of the local application of croton oil in acetone than the skin of animals which received the same diet except for the isocaloric substitution of sucrose for the lard.

The nature of the histopathologic changes which have been shown to result from the lack of unsaturated fatty acids in the diet of animals is such that it is very unlikely that these will prove to be of any value in the recognition of a fatty acid deficiency in human subjects. The metabolic response as evidenced by the respiratory quotient in an adult subject on the fat free diet was similar to that observed in rats on a fat free diet. Nothing is known regarding interrelationships between the unsaturated fatty acids and the various vitamins in human subjects, although an extensive literature is accumulating from animal experiments. For example, the specific good effect of linoleic acid on the skin is particularly striking in the complete prevention of the severe acrodynia accompanying pyridoxine deficiency in rats.[30]

Perhaps one of the greatest difficulties in ascertaining the essential nature of certain unsaturated fatty acids in human subjects may be attributed to the inability to measure accurately the content and distribution of linoleic and arachidonic acid in the blood and tissues. It is very striking, however, that changes in the pattern of the serum lipids are the same in human subjects as in experimental animals. Although by the bromination technic the tetrabromides and polybromides of serum were demonstrated to be reduced on a fat free diet, this cannot be taken as absolute evidence that the human subject has a special need for linoleic or arachidonic acid. This finding, however, together with various serum lipid studies, gives strong support to the theory that the human organism is unable to synthesize the unsaturated fatty acids which have been found to be essential for some animals. The adaptation of spectroscopic methods to the quantitative measurement of linoleic and arachidonic acids in human serum and tissue promises to aid further studies of the need for and the specific function of the essential fatty acids in human nutrition.

ANTIBIOTICS AND THE CENTRAL NERVOUS SYSTEM

Rammelkamp and Keefer[1] demonstrated that penicillin does not pass through the blood-brain barrier in significant quantities following an intravenous injection of the substance. In normal subjects penicillin appeared to be slowly absorbed and slowly excreted in the urine following intrathecal injection of 5,000 or 10,000 Florey units. In subjects with meningitis, absorption of penicillin after intrathecal injection is more rapid than in normal persons. Injection of 10,000 Florey units in a normal volunteer was followed by headache, vomiting, increased intrathecal pressure and phagocytosis in the spinal fluid. After the injection of 5,000 Florey units, symptoms were not noted other than a slight headache and a slight increase in the number of leukocytes in the spinal fluid. In subjects with meningitis untoward symptoms were not noted following the injection of 10,000 Florey units. Sweet and his co-workers[2] recorded 2 instances of mild and 2 of severe sacral radiculitis following intrathecal injections of penicillin in 16 patients with pneumococcic meningitis. All these patients recovered. McCune and Evans[3] resorted to intraventricular injection of penicillin in a case of staphylococcic meningitis which did not respond to intravenous injections of sodium sulfadiazine and to repeated intrathecal injections of penicillin. A needle passed into the right ventricle of the brain yielded 8 cc. of slightly turbid, colorless fluid which showed only minimal bacteriostatic activity in spite of the fact that 7,500 units of penicillin had been introduced by lumbar puncture two hours earlier. Then 7,500 Florey units of penicillin was dissolved in 5 cc. of saline solution and introduced into the ventricle. There was no immediate reaction to the procedure. There was a definite improvement in the general condition of the patient, leading to complete recovery. These authors suggest that intraventricular use of penicillin may be resorted to as an adjunct to the intrathecal route of administration without untoward reactions and with good effect. A patient with Staphylococcus albus infection of the ventricular system was treated by Johnson and Walker[4] with 50,000 Oxford units by intraventricular injection. Within one hour the patient was comatose and in vascular collapse. For the next several hours he had clonic spasms of the arms, legs and neck. Within a day the patient appeared normal. Two days later 15,000 Oxford units of penicillin was injected into the right lateral ventricle. Four hours later the patient had twitchings of the right arm and leg which disappeared within a few hours. After further intraventricular injections of penicillin without reaction, the patient recovered completely.

Johnson and his co-workers[5] found that in the dog and the monkey approximately 500 Oxford units of penicillin applied to the cerebral cortex is sufficient to induce convulsive manifestations, which initially consist in chronic spasms of the contralateral extremities but later involve all the limbs in the manner of a generalized epileptic seizure. In man the convulsive threshold appears to be considerably higher. These toxic manifestations are not due to impurities in the penicillin, for pure crystalline penicillin induces the attacks. It appears from these experiments that penicillin when applied to the central nervous system in adequate amounts which, the authors stress, fortunately are far above therapeutic requirements, will induce convulsive manifestations which usually are of a temporary nature. These clinical fits are accompanied with the electroencephalographic manifestations which characterize epileptic attacks. Investigation of other antibiotics revealed that streptomycin applied to the central nervous system will induce mild convulsive manifestations of a temporary nature. The clinical and electroencephalographic manifestations are less severe than those produced by equivalent doses of penicillin. Streptothricin, actinomycin and clavacin, when directly applied to the central nervous system in large doses, likewise show convulsive propensities. Penicillin and streptomycin may be applied to the central nervous system without toxic effects in doses far above an adequate antibiotic concentration, whereas streptothricin, actinomycin and clavacin appear to produce severe toxic effects in concentrations little, if at all, above therapeutic levels. These antibiotic substances would not be acceptable for clinical use in the central nervous system even if they were free from systemic toxic effects. As far as penicillin and streptomycin are concerned, the margin between the therapeutic concentration and the convulsive threshold is so great that with reasonable care the toxic effects should be avoidable.

CARDIAC DEPLETION ALLERGY

Study of the effects of bacterial toxins on the isolated vertebrate heart has led to the discovery of two types of cardiotoxins. The first type is illustrated by the action of Clostridium septicum toxin. Perfused through the isolated frog heart, this bacterial filtrate causes a progressive systolic and diastolic decrease. At the end of twenty minutes the ventricle usually stops beating midway between systole and diastole. A second type of cardiotoxin was recently described by Bernheimer and Cantoni [1] of the Departments of Bacteriology and Pharmacology, New York University College of Medicine. This type is illustrated by cardiotoxic filtrates from Streptococcus pyogenes and the type II pneumococcus.

In a typical experiment a dialyzed streptococcus filtrate was diluted twenty-five times with isotonic solution of three chlorides containing cysteine in a concentration of 1:1,000. The solution was administered by means of a Fühner cannula to an isolated frog heart and allowed to remain in the heart for twenty-three minutes. Even a suggestion of a toxic reaction was not recorded in the course of several hundred experiments. At the end of twenty-three minutes the solution was removed and the heart twice washed with the isotonic solution. A second dose of a toxic filtrate identical with the first was now introduced into the Fühner cannula. Within thirty seconds decreased relaxation of the ventricle occurred, increasing to a complete systolic contracture by the end of ninety seconds.

This toxicity cannot be explained as a result of summation of the two toxic doses. Control normal hearts tested with ten times the sum of the two doses did not show any suggestion of a systolic contracture. The phenomenon is apparently a true sensitization of the myocardium due to the initial contact with the dilute toxin. Similar sensitizations were demonstrated with type II pneumococcus filtrate and with preparations of Clostridium welchi theta toxin.

Analysis of this allergic phenomenon [2] shows that the myocardium, as a result of the initial contact with streptococcus filtrate, releases an inhibitory substance into the perfusion fluid in sufficient quantities to neutralize from five to ten times the routine toxic dose. Subsequent washings with isotonic solution of three chlorides remove nearly all of this toxin inhibitor. The depleted heart thus becomes hypersensitive to a second application of the same cardiotoxin.

Release of this toxin inhibitor was confirmed on mice. Intravenous injection of 0.5 cc. of a 1:25 dilution of streptococcus filtrate kills 16-20 Gm. mice within five minutes. Addition of from 0.125 to 0.5 cc. of inhibitor fluid from a perfused frog's heart usually prevents this toxic reaction completely, two third of all animals surviving indefinitely.

The toxin inhibitor is nondialyzable through a cellophane sac and is relatively heat stable, its inhibiting titer being only slightly reduced by heating to 100 C. for thirty minutes. The inhibitor is soluble in chloroform. By means of chloroform it can be extracted and recovered almost quantitatively from transfusion fluid. The stability of the inhibitor toward heat and its solubility in chloroform clearly set it apart from antibodies in the usual sense of the term.

From the point of view of immunologic theorists the local formation or release of inhibitor substances from the heart muscle is a most important addition to current theories of immunochemistry. Whether or not tissues other than the myocardium synthesize or release similar toxin inhibitors has not yet been determined.

"WETZEL'S GRIDS" IN PEDIATRIC ENGINEERING

Disease and its treatment, as Blackfan [1] pointed out, "are overshadowed by the problems of growth and development which . . . provide added duties for every physician who undertakes to furnish medical care for children—duties which in olden times were not required." None knew better than he the difficulties of these problems and the limitations of methods then available to deal with them. Now the Wetzel baby grid [2] as an introduction to pediatric engineering is conceived to be a practical method of surmounting the obstacles that have hindered physicians in judging the outcome of their efforts to promote sound growth.

This baby grid, which Wetzel describes as "a direct reading control chart on the quality of growth and development in individual infants," is an extension of principles and technic whose practical value in older children was recognized and commented on by THE JOURNAL [3] some years ago. More recently, in a significant critique contrasting the appraisal of human growth with the less complicated problem in cattle, Samuel Brody, student and investigator of bioenergetics and growth, remarked that "Wetzel gave the best expression to the weight-height-age status." The grid, according to Brody,[4] represents a "unique contribution . . . [which] brings together the weight, height, age and also metabolism data in one conveniently designed chart." There would seem to be good reason for physicians practicing pediatrics to look on the baby grid as Brody does on its forerunner.

---

[1] Blackfan, Kenneth D.: Introduction to Pediatrics, in Brennemann's Practice of Pediatrics, Hagerstown, Md., W. F. Pryor Company, Inc., 1945, vol. 1, chapter 2, p. 1.

[2] Wetzel, N. C.: The Baby Grid, J. Pediat. **29**:439 (Oct.) 1946.

[3] Physical Fitness from Two to Twenty, editorial, *J. A. M. A.* **116**:1223 (March 22) 1941.

The practical philosophy behind a baby grid is both interesting and instructive. Wetzel takes the point of view of an engineer confronted with the economic problem of controlling the quality of a factory's product where failure to do so would result in "going out of business."[5] He views the infant as the analogue of the factory, the infant's growth as the analogue of factory output. The aim in each case is to maintain "top quality" production and to know whether this is being done. In an infant, even in small premature babies, growth quality is directly gaged by the "fidelity" with which a baby conforms to the "tolerance limits" for speed and direction as patterned in the grid. Healthy infants exemplify, as Wetzel believes, a fundamental law that "growth is a moving and not a static function in babies." Those whose growth is faulty—the engineer's "rejects"—are identified by their departure from that law. As a further tie-in with the engineering approach, such matters as body surface, size and shape as well as energy requirements are also provided for in this one page compendium of infant growth. The physician can evaluate his data on a baby grid without indulging in the statistical pyrotechnics of other methods that are so oblivious to practical considerations as to require that a doctor manipulate sigmas, t-scores or similar paraphernalia of investigative research.

By coincidence the baby grid appears as the American Academy of Pediatrics is in the midst of its earnest, forward looking study of child health services.[6] While these efforts are more immediately concerned with gathering factual data for scientific planning of postwar infant and child care, the ultimate results will sooner or later affect millions of children whose natural right is the opportunity to achieve "top quality growth." But that result, as Wetzel shows, "presumes knowledge on how well a given baby is fulfilling its own capacity for growth." The engineering equipment required for this particular job seems now to be at hand in the form of the baby grid. Pediatricians will utilize this simple precision instrument as an aid in their work with babies, just as the American Association of Teachers Colleges has found the "big grid" useful in their own new curricular emphasis on the growth of school children.[7]

Current Comment

ENVIRONMENT AND PHYSIQUE

The relation between environment in the broad sense and the physical development of human beings has been the subject of many scientific studies and much speculation. Recently Lasker[1] made physical measurements on 284 adult Chinese, 97 of whom were Cantonese immigrants, 48 American born Chinese of Cantonese extraction, 5 Hawaiian born Chinese, 9 Cantonese born elsewhere and the remainder from other parts of China. The standard methods of examination described by Martin[2] were followed, with a few exceptions. Certain differences in physique of Chinese men born and raised in the United States were found as compared with Chinese immigrants born in China. These differences included an increase in the stature and in all the measurements correlated with stature, such as trunk and limbs, other than chest depth. The thoracic, brachial, hand and foot indexes tended to be lower in the Chinese of American birth. The American born Chinese had wider and shorter heads and longer, narrower, higher noses and longer faces. Lasker concluded that the typical oriental youth brought up or born in the United States or Hawaii differed from immigrants of like stock in what he calls an "environmental growth factor." The former is taller with longer arms and legs, relatively smaller hands and feet and flatter chest. His head is likely to be shorter but broader and the nose relatively narrower. More body hair is in evidence. The changes noted in the Chinese born in the United States seem to reflect a process caused by changed diet or other factors incident to the migration of peoples. Whether such physical changes as exist are due primarily to diet, to climate or to other environmental factors would be interesting to investigate though extremely difficult to determine.

THE EYE BANK

The Eye Bank for Sight Restoration, Inc., established in 1944 in New York City, was conceived as a centralized agency where eyes could be systematically salvaged, preserved and redistributed to doctors who perform the corneal grafting operation. Originally twenty leading ophthalmologists in key cities throughout the country acted as advisers and interpreters of the program. At present over two hundred and thirty-seven doctors are serving throughout the nation. To the initial twenty-two prominent New York hospitals that participated in the project at its inception there have been added fifty-six hospitals throughout the country. Transportation for incoming and outgoing eye material has been made available through the cooperation of the American Red Cross and various airlines. In addition to supplying corneas for surgical procedures, the eye bank has carried on a widespread program of education both of the public and of physicians through the press, magazines, the radio and the distribution of literature. During the first year of activity nine

scholarships were awarded to ophthalmologists, who, after their training, will return to states throughout the country to be associated with medical centers. In addition, two fellowships have been granted. The facilities of the Ayer Laboratory for Corneal Research have been made available for routine and investigative work. Here the eyes are received, given a prompt and careful examination to determine the condition of the corneal tissue, put under a twenty-four hour culture test and then sent with directions to doctors for grafting operations. After the corneal tissue has been used the eyes receive a pathologic examination, and the results of this are reported to the hospital or doctor whence the eyes originated. Challenging research problems which have been attacked include studies on corneal preservation, technics of transplanting the vitreous humor and investigations of the metabolic and histologic properties of the eye. An information kit of educational material may be obtained by writing to the Eye Bank for Sight Restoration, Inc., 210 East 64th Street, New York 21.

VACCINATION FOR MUMPS

Active attempts are now being made to develop a satisfactory vaccine against mumps. Recently Stokes and his colleagues[1] reported on the use of formol-inactivated suspension of mumps virus as a vaccine against mumps. Four groups of children were studied who were inmates of three institutions. A negative complement fixation test was the only criterion of susceptibility in the selection of the first two groups. In the third group this test was used and also, as a further check on susceptibility, skin tests. The fourth group consisted of those who at the beginning of the experiment were found to be negative both by complement fixation and by skin test. In the first, second and fourth groups approximately half of the children were given suspension of mumps virus inactivated by the addition of formol. The remaining children were controls. In the third group about two thirds of the children were vaccinated. The vaccine was administered in the first, second and fourth groups by a subcutaneous route in two doses each of 0.3 cc. of a 10 per cent and of 0.5 cc. of the 2.5 per cent suspension at an interval of five days. The period for testing the vaccinated group was fourteen to seventeen days from the date of first injection of the vaccine. The virus employed in testing the efficacy of vaccination was introduced by injection directly into Stensen's duct or by spray. A variable degree of swelling of the inoculated parotid gland appeared after the injection of virus in all of those who received the virus by direct inoculation. However, the interval between the inoculation with live virus and the time at which the maximal enlargement of the gland was noted varied considerably in the vaccinated and the control groups. About four fifths of the vaccinated may be considered to have exhibited evidence of resistance as compared with about one fourth of the controls. The principal conclusion from the study was that vaccination with formol inactivated virus apparently leads to increased resistance in about half of the children whose immunologic status was subsequently tested by experimental inoculation of pathogenic material. The degree of protection in human beings afforded by the formolized vaccine is therefore of about the same degree as that observed in monkeys vaccinated in the same manner.

PHYSIOLOGIC STANDARDS IN ADOLESCENCE

Pediatrics has been well established for many years; geriatrics is making a bid for recognition; specialty practice outside the pediatric and geriatric age groups is concerned with adult patients. There remains, however, a special age group which has peculiar physiologic, pathologic and psychologic problems. Significant studies are now appearing regarding these important medical factors in adolescence.[1] Among these the surveys made by Nathan W. Shock[2] are particularly important. These studies were initiated by the Institute of Child Welfare at the University of California and have been continued under the direction of the National Institute of Health. Shock emphasizes the difficulty of establishing adequate standards for physiologic factors in adolescence. Shuttleworth[3] in 1938 demonstrated the serious limitations of average values usually regarded as "age norms" obtained from averages of different children measured at successive ages. Repeated measurements on the same children during growth have shown the individuality of the growth process. Shock emphasizes that the rapidly maturing adolescent may find himself in difficulties because adults expect from him behavior or performance consistent with his size. Since size and social or intellectual maturity do not necessarily proceed together, it often happens that the "large" adolescent is relatively immature. Thus he may be unable to meet the expectations of adults with respect to performance or behavior. The failure to "deliver" in the eyes of his peers or of adults is not an uncommon source of psychologic tensions. Probably inadequacy felt or observed by many adolescents has a definite physical or physiologic basis, but the nature of the factors concerned may vary widely among different boys and girls. Knowledge of individual differences in rates of maturing, as illustrated by the observations reported by Shock, can do much to minimize the emphasis placed all too often by school physicians and councilors on attaining "normal" values. The pediatrician is in a strategic position to aid developing adolescents in understanding and evaluating their own development.

ORGANIZATION SECTION

Official Notes

RESOLUTIONS TO BE PRESENTED TO HOUSE OF DELEGATES

The following resolution will be presented to the House of Delegates at the Supplemental Session, December 9 to 11, by the Indiana delegation:

Resolution on National Conference of County Medical Society Officers

WHEREAS, Public relations, as pertains to organized medicine, has a most important field of effort in reaching and giving information to and receiving suggestions from the rank and file of doctors who give medical service to the public the country over, and

WHEREAS, Efforts in this direction have been so successfully carried on by the secretaries' conferences sponsored by several of the state medical societies, and

WHEREAS, There is no national group at present functioning in this capacity, therefore be it

Resolved, That the American Medical Association sponsor a national conference of officers of county medical societies which shall meet yearly just preceding the annual session of the House of Delegates of the American Medical Association for the purpose of bringing to the annual session the diverse problems of the various localities, the exchange of ideas which would be helpful to the state conferences, in such matters as voluntary health insurance plans, hospitalization plans, construction of new hospitals in needed places, and improvement in medical facilities, rural health activities, nursing activities and the activities of the various Councils of the American Medical Association

Dr. E Vincent Askey, delegate of the California Medical Association, will present the following resolution

Resolution on Requirements for Approval of Hospitals

WHEREAS, The problem of hospitalization is urgent now and will be distressingly difficult for an indefinite period of time, and

WHEREAS, There is apparently a definite plan to limit staff membership in hospitals to diplomates of the various specialty boards, and

WHEREAS, The limiting of staff memberships and heads of departments of such staffs in hospitals to such diplomates could tend to injure the best interests of the public and the medical profession as a whole, and

WHEREAS, Of a total of 180,000 physicians in the United States approximately only 22,000 are diplomates of all specialty boards, and limitation by the hospitals of their facilities to use by these few would work an injustice on other capable doctors and their patients, therefore be it

Resolved, That the House of Delegates of the American Medical Association suggests to the Council on Medical Education and Hospitals and directs it to further the realization of this suggestion, to wit

The requirements for approval of hospitals shall be so defined that there shall be (1) adequate protection of the rights of all doctors and their patients in obtaining hospitalization to the end that general practitioners as well as specialists shall have access to and use of hospital facilities, (2) that the criterion of whether a doctor may be a member of a staff or head of a department shall be his actual ability as a doctor and not dependent on special society or board membership, and (3) that the American College of Surgeons be urged to conform to these general policies in its procedures in the standardization of hospitals

Coming Medical Meetings

American Medical Association House of Delegates Supplemental Session, Chicago, Dec 9-11. Dr. George F. Lull, 535 N Dearborn St, Chicago 10, Secretary.

Conference of State Secretaries and Editors, Chicago, Dec 7-8. Dr. George F. Lull, 535 N. Dearborn St, Chicago 10, Secretary.

American Academy of Dermatology and Syphilology, Cleveland, Dec 7-12. Dr. Earl D Osborne, 471 Delaware Ave, Buffalo, N Y., Secretary.

American College of Surgeons, Cleveland, Dec. 16-20 Dr. Dallas B. Phemister, 40 E Erie St, Chicago 11, Secretary.

American Society of Anesthesiologists, New York, Dec 12 Dr. Curtiss B. Hickcox, 745 Fifth Ave, Room 1503, New York, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 13-15 Dr Rafael A. Vilar, P. O Box 3866, Santurce, Secretary.

Southeastern Allergy Association, Atlanta, Ga, Jan. 18-19 Dr. Katharine B MacInnis, 1515 Bull St, Columbia 49, S C, Secretary.

Southern Surgical Association, Hot Springs, Va, Dec. 10-12. Dr. Alfred Blalock, Johns *Hopkins Hospital,* Baltimore 5, Secretary.

Washington Letter

(From a Special Correspondent)

Dec. 2, 1946.

Insulin Increased 50 Per Cent in Price Without Price Control

Increases of 50 per cent in the price of insulin are reported by producers, following the removal of price controls here. Eli Lilly and Company of Indianapolis has announced an increase of this amount and the other manufacturers are reported to be following suit The drug is a necessity to around a million diabetic sufferers in this country. Industry spokesmen say that the rise in price is necessary because of the increased demand for beef and pork pancreas glands, the raw material for insulin, and because of new uses for insulin as well. The glands also have new uses in protein extracts for supplemental diseases Insulin was for long under close price control

Medical Center May Be Patterned After Massachusetts General Hospital

The $20 million hospital center to be erected in the nation's capital may be patterned after the Massachusetts General Hospital in Boston, which has separate medical and surgery buildings, is erecting a building for women's diseases, has two private patient buildings on luxury and middle income levels, and operates separate institutions for mental patients and tumor research and treatment The three Washington hospitals involved in the Washington center may have functions allocated as follows· Emergency, devoted to surgery, Garfield, devoted to medicine, and Episcopal Eye, Ear and Throat continuing present specialized services Emergency and Garfield hospitals must continue as separate entities to keep endowments and present operating funds.

Cancer Society Incorporates District of Columbia Division

Dr. H. H. Kerr, president of the newly incorporated District of Columbia Division of the American Cancer Society, said that the group plans a "really effective cancer control program" Washington's first organized program against cancer will be preceded by a survey of cancer needs to be paid for by the U. S Public Health Service The survey director will be chosen by District Health Officer Ruhland from a list of experts compiled by Dr Calvin T. Klopp, director of the Warwick Memorial Cancer Clinic in Garfield Hospital

Psychiatric Foundation Organized

Following the example of tuberculosis, cancer and infantile paralysis movements, the Psychiatric Foundation, a nonprofit corporation, has been formed to fight mental illness The foundation is composed of laymen and specialists The group has the endorsement of the American Psychiatric Association, the American Neurological Society and the National Organization of Public Health Nursing

Walter Reed Hospital Faces Cuts in Funds and Personnel

The economy program of the Army is expected to cause further cuts in budget and personnel of Walter Reed Hospital, although both categories have already been reduced by about 25 per cent, it is reported There is not expected to be a reduction in the patient load at the hospital because temporary hospitals throughout the country are being closed and some of their patients are coming to Walter Reed

Predicted Influenza Epidemic Is Slow in Arriving

The U S Public Health Service has indicated that a predicted influenza epidemic is slow in materializing. There were 2,104 cases throughout the nation for the week ended November 16, which is about half the number of cases reported for the same week last year. Of the recent total Texas reported 1,039, Virginia 317, North Carolina 309 and Arizona 130.

GOVERNMENT SERVICES

ARMY

29TH GENERAL HOSPITAL (THE COLORADO UNIT) SCHEDULED FOR INACTIVATION

The 29th General Hospital, chief army medical installation in southern Korea, will be inactivated before December 15. Activated as a 1,000 bed general hospital on Sept. 1, 1942 at Fort George Meade, Maryland, this hospital drew its professional personnel from the University of Colorado School of Medicine, Denver. The unit arrived at New Caledonia on Nov. 21, 1943, and more than 12,000 casualties from Bougainville, Munda, Saipan, Leyte, Peleliu and other South Pacific campaigns were treated at this hospital. In April 1945 the unit was ordered to Okinawa and in October of that year to Seoul, Korea. The hospital has given general hospital type care to members of the occupation in Korea since then.

The commanding officer of the 29th General Hospital while in the South Pacific was Col. William C. Pollack. Lieut. Col. John M. Foster was in command from July 5, 1944 to November 1945 and Col. Jonathan M. Rigdon from December 1945 to July 1946. From August to September 1946 Major Harold V. Ellingson, Cleveland, who is still with the hospital, was in command. The present commanding officer is Lieut. Col. William B. Stryker of St. Paul.

The hospital was awarded the Army Meritorious Service Unit Plaque July 30 of this year for superior performance of duty in the execution of exceptionally difficult tasks in New Caledonia from January to April 17, 1945.

MEETING AT 42D GENERAL HOSPITAL IN JAPAN

About 150 army doctors of the Tokyo-Yokohama area held the regular bimonthly meeting November 13 at the 42d General Hospital. Addresses were given by Col. C. L. Gandy, Ocean View, N. J., commanding officer, 42d General Hospital; Col. P. L. Cook, Wyalusing, Pa., surgeon, Eighth Army; Brig. Gen. J. A. Bethea, U. S. Army, Marion, S. C., chief surgeon, A. F. P. A. C.; Capt. M. H. Paushter, Springfield, Mass., on Methyl Alcohol Poisoning; Capt. M. C. Blanchard, Columbus, Ga., Infectious Mononucleosis; 1st Lieut. Edmunds G. Dimond, Indianapolis, Mediastinal Emphysema; 1st Lieut. Alan Davidson, St. Albans, Vt., Management of Foreign Bodies in the Eye; Capt. G. O. Wellman, Hurricane, W. Va., Gunshot Wounds of the Abdomen and Rupture of the Liver; 1st Lieut. Walter J. Wilkins, Poplar Bluff, Ark., Rupture of the Duodenum; Capt. Donald E. Preshaw, Detroit, Atelectasis with Pleural Effusion; Capt. Chester B. Powell, Chicago, Management of Head Injuries; Capt. Thomas H. Williams Jr., Montgomery, Ala., Management of Injuries to the Genitourinary Tract, and 1st Lieut. H. I. Posin, New York, of the 361st Station Hospital, Epilepsy.

PROFESSIONAL ACTIVITIES AT HALLORAN GENERAL HOSPITAL

A special week of professional activities began at U. S. Halloran General Hospital, Staten Island, New York, on November 18. Following a series of rounds in the Dermatology and Medical buildings and clinics in orthopedic and neurosurgery, a conference was addressed by Dr. Harry Gold, associate professor of pharmacology, Cornell University Medical College, on treatment of cardiac failure. At a conference on the following day, with clinics and rounds, Dr. Hirsh Liebowitz, instructor of medicine, New York University College of Medicine, discussed the treatment of peptic ulcer. A film on bronchial asthma was presented and a symposium on preoperative orthopedics. Other activities during the week comprised a cardiac fluoroscopy clinic, rounds in general surgery and postoperative neurosurgery and orthopedic postoperative evaluation, all under the general supervision of Col. O. H. Stanley, M. C., U. S. Army, commanding officer of the hospital.

GENERAL KIRK AWARDED CROSS OF LEGION OF HONOR

Major Gen. Norman T. Kirk, the Surgeon General of the United States Army, was recently awarded the Cross of the Legion of Honor in the degree of Commander at the office of the French military attaché, Washington, D. C. In the same ceremony the degree of Chevalier was awarded to Brig. Gen. Raymond W. Bliss, Deputy Surgeon General of the United States Army. The presentations were made by the Surgeon General of the French army, Gen. Raymond Debenedetti, who was accompanied by Col. Alexander Ribollet and Major Pascaul Santini, French staff officers.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Robert M. Hardaway

The Legion of Merit was recently awarded to Brig. Gen. Robert M. Hardaway, M. C., U. S. Army, of Washington, D. C., "for exceptionally meritorious service as commanding general, Bushnell General Hospital, from August 1942 to January 1946. General Hardaway's sound foresight and effective planning" was credited in the citation as resulting "in the highest type medical and surgical treatment for all patients. He developed a superior program for amputee patients throughout the Ninth Service Command. Through extensive professional knowledge, initiative and unremitting devotion to duty, he provided these patients with a highly efficient method for training in the use of artificial limbs." Dr. Hardaway graduated from Washington University School of Medicine, St. Louis, and entered the service May 25, 1912.

Colonel Charles T. Young

The Oak Leaf Cluster to the Legion of Merit was recently awarded to Col. Charles T. Young, M. C., U. S. Army, of Washington, D. C., for meritorious service from March to October 1945 as commanding officer, Wakeman Convalescent Hospital, where "he displayed a high type of organizational ability and leadership." The citation also states that "by reason of his judgment, energy and superior force and leadership Colonel Young was responsible for the outstanding qualities of Wakeman Convalescent Hospital, and contributed materially to the war effort." Dr. Young graduated from John Hopkins University School of Medicine and entered the service Aug. 3, 1928.

Lieutenant Colonel Weldon K. Ruth

The Bronze Star was recently awarded to Lieut. Col. Weldon K. Ruth, M. C., U. S. Army, of O'Keene, Okla., who "performed meritorious and heroic services from April 10 to 22, 1942 during the march of captured Americans from Bataan Province to Japanese concentration camp near Capas, Tarlac, Philippine Islands." Lieutenant Colonel Weldon was cited for disregarding his own condition and risking brutalities and death at the hands of the Japanese by continually attending his sick, exhausted comrades. "He prevented the murder of two officers on separate occasions by interposing his body between them and enemy soldiers until he could revive them enough to continue the march. Major Ruth's ministrations did much to alleviate the suffering of his fellow prisoners of war." Dr. Ruth graduated from the University of Oklahoma School of Medicine, Oklahoma City and entered the service Dec. 7, 1936.

NAVY

ADMIRAL SWANSON TO SUCCEED ADMIRAL McINTIRE AS SURGEON GENERAL

President Truman on November 27 appointed Capt. Clifford A. Swanson Surgeon General of the Navy and chief of the Bureau of Medicine and Surgery, with the rank of Rear Admiral. Admiral Swanson, whose selection is a recess appointment pending confirmation by the Senate, will succeed Vice Admiral Ross T. McIntire, who has held that position since his appointment by President Roosevelt on Dec. 1, 1938. Admiral Swanson is from Marquette, Mich., and graduated from the University of Michigan Medical School, Ann Arbor, in 1925. He is a member of the American Academy of Ophthalmology and Otolaryngology and has been certified by the American Board of Otolaryngology. He entered the medical corps of the Navy in June 1925.

Admiral McIntire, a native of Oregon, graduated in medicine in 1912 from the Medical School of Willamette University, now the University of Oregon School of Medicine. He was the first Surgeon General of the Navy to be born west of the Rocky Mountains. In addition to the duties of Surgeon General and chief of the Bureau of Medicine and Surgery, he served also as White House physician. His present appointment expired November 1. Mr. Truman provided that Admiral McIntire will retain the rank of Vice Admiral when detached from his present duties. Admiral McIntire was also a specialist in ophthalmology and otolaryngology. He is due to retire in a short time, when he will have completed thirty years of active duty in the Navy.

NAVY AWARDS AND COMMENDATIONS

Captain Frederick L. McDaniel

The Commendation Ribbon was recently awarded to Capt. Frederick L. McDaniel (MC), U.S.N., "for conspicuous and outstanding service as senior medical officer of the U. S. S. *Benevolence* when that hospital ship was suddenly and without forewarning called on to screen, treat and otherwise care for the first 1,500 Allied prisoners of war released from Japanese prison camps in the Tokyo Bay area. Subsequently," continues the citation, "under his able professional supervision the many hundreds of seriously ill American prisoners of war were afforded the highest type of medical skill and treated with most meticulous and kindly service. The quality of leadership demonstrated by Captain McDaniel was an inspiration to his staff associates and a reassurance to the suffering prisoners of war. His conduct was at all times in keeping with the highest traditions of the United States Naval Service." Dr. McDaniel graduated from the University of Maryland School of Medicine in 1913 and entered the service in May 1917.

PERSONAL

The Bureau of Medicine and Surgery announced the assignment of Commander James A. Grindell (MC), U.S.N., to the Massachusetts General Hospital, Boston, for a course in cardiology.

PUBLIC HEALTH SERVICE

FELLOWSHIPS IN HEALTH EDUCATION

Fellowships leading to a Master's Degree in Public Health in the field of Health Education are being offered to any qualified United States citizen between the ages of 22 and 40, according to a statement by the U. S. Public Health Service. Tuition, travel expenses for field training and a stipend of $100 a month will be provided out of funds furnished by the National Foundation for Infantile Paralysis. Candidates must hold a bachelor's degree from a recognized school and must be able to meet the entrance requirements of the accredited school of public health of their choice. In addition, courses in the biologic sciences, sociology and education may be required. Training in public speaking, journalism, psychology and work in public health or a related field are considered desirable qualifications.

The year's training, which begins with the 1947 fall term, consists of eight or nine months' academic work including public health administration, epidemiology, public health and school education, problems in health education, community organization and information technics and three months of supervised field experience in community health education activities. Application blanks may be obtained by writing the Surgeon General, United States Public Health Service, Washington 25, D. C., and must be filed prior to March 15, 1947.

Veterans are encouraged to apply and will be paid the difference between their subsistence allowance under the G. I. Bill of Rights and the monthly stipend of $100. Employees of local and state health departments are not eligible, since federal grants-in-aid are already available for such training purposes.

GRANTS FOR CANCER RESEARCH

The U. S. Public Health Service has announced that grants-in-aid amounting to about $200,000 have been recommended by the National Advisory Cancer Council for the support of cancer research projects in twenty-one universities, hospitals and research institutions. The variety of projects covered by the grants illustrate the complexity of the cancer problem and the many angles from which research must be carried on to solve it. The grants were recommended at the thirty-second meeting of the council held November 8 at the National Cancer Institute, Bethesda, Md., and presided over by Dr. James A. Crabtree, Acting Surgeon General, U. S. Public Health Service. The members of the National Advisory Cancer Council are Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, who is chairman ex officio and in whose absence Dr. Crabtree presided; Dr. George M. Smith of Yale University, executive director of the council; Dr. Frank E. Adair, president of the American Cancer Society, New York City; Dr. A. C. Ivy, acting dean, University of Illinois Medical School, Chicago; Dr. Charles B. Huggins, professor of surgery, University of Chicago School of Medicine, Chicago; Dr. Sherwood Moore, director of the Mallinckrodt Institute of Radiology, Washington University, St. Louis, and Dr. Robert S. Stone, professor of radiology, University of California Medical School, San Francisco.

NEW ASSISTANT CHIEF, BUREAU OF STATE SERVICES

Dr. Herman Hilleboe has been appointed to the newly created post of assistant chief, Bureau of State Services, United States Public Health Service. Dr. Hilleboe will continue to discharge his regular duties as chief of the Tuberculosis Control Division. A graduate of the University of Minnesota Medical School and of the School of Public Health at Johns Hopkins University, he has been in public health activities since 1933, when he was appointed director of the Minnesota State Division of Tuberculosis Control. In 1937 he became special consultant in tuberculosis to the National Institute of Health and in 1939 became senior assistant surgeon in the Regular Corps of the Public Health Service. He was appointed by the Secretary of State to attend the fourth World Conference of Workers for Crippled Children in London, England, and, while abroad, inspected tuberculosis control programs in England, Germany, France and the Scandinavian countries. In 1942 Dr. Hilleboe was assigned to duty in the Public Health Service and made medical officer in charge of the Tuberculosis Control Section, States Relations Division. In 1944 he was appointed chief of the newly created Tuberculosis Control Division, with the rank of medical director.

VETERANS ADMINISTRATION

THE HOME TOWN MEDICAL CARE PROGRAM

Dr. Paul R. Hawley, medical director of the Veterans Administration, explained on November 14 the extent of the medical services which may be rendered to veterans under the home town medical care program. Existing legislation provides that veterans may be furnished outpatient medical or dental treatment in VA clinics, in private offices of physicians or dentists, or in their own home *only for disabilities recognized by VA as incurred or aggravated in line of duty in active service.* Only prescriptions for service connected disabilities may be filled at government expense by local pharmacies under VA's home town prescription service. The medical facilities of VA regional and subregional offices, clinics and hospitals under law must be utilized to the fullest extent for examination and outpatient treatment of veterans. When it has to be determined whether a veteran residing in an area where there is a VA field station (such as a clinic or a hospital) is to be referred to a VA clinic or to a civilian physician, the best interest of both the veteran and the government will be considered.

If veterans establish to the satisfaction of the chief medical officer of a VA regional office that reporting to a field station would work unnecessary physical hardship or cause excessive loss of time from employment, fee-basis doctors may be utilized. In any event, final decision rests with chief medical officers of VA regional offices. Then too, when the backlog of physical examinations justifies or when outpatient treatment is not being rendered expeditiously, the chief medical officers of VA regional offices may utilize the services of civilian physicians working under statewide contracts with the Veterans Administration.

Male veterans may be admitted to private hospitals (preferably those under contract by VA) for inpatient treatment of service connected disabilities by civilian physicians under contract to VA only if their condition is such as to constitute an emergency which cannot be met by a VA hospital because of the lack of beds or because the patient's condition prohibits travel. Prior authorization for this hospitalization and treatment in a private hospital must be obtained. If, owing to the extreme emergency of the case, prior authorization is not obtained, the physician or admitting hospital should notify VA within seventy-two hours. If the facts so warrant, VA will issue authority for the veterans's private hospitalization and treatment. Women war veterans may be admitted to private hospitals (preferably those under contract by VA) for inpatient treatment of *both service connected and non-service connected disabilities* by civilian physicians if it is an emergency which cannot be met by VA or because of the unavailability of beds or because the serious condition of the patient precludes travel. Authorization must be obtained exactly as in the case of male veterans.

CONTRACT WITH WEST VIRGINIA MEDICAL ASSOCIATION

Dr. Andrew E. Amick, president of the West Virginia State Medical Association, has appointed a board of review under the provisions of the contract between the association and the Veterans Administration. The board is composed of Drs. Claude B. Smith and Paul H. Revercomb of Charleston and James R. Brown of Huntington. The board will review reports which are deemed by the Veterans Administration to be inadequate or which do not meet the requirements of the Veterans Administration, recommend, at its discretion, the disqualification of any physician from further work with the Veterans Administration whose work is found by the board to be unsatisfactory, and advise and assist the Veterans Administration in other matters within the scope of the program.

With the signing of the contract the work of the Veterans Affairs Committee was completed. This committee, which has functioned since early in the year, was composed of Drs. Claude B. Smith, Charleston, chairman; C. O. Post, Clarksburg; Thomas L. Harris, Parkersburg; Francis A. Scott, Huntington, and Ralph J. Jones, Charleston. As of November 15, 809 members of the West Virginia State Medical Association have been certified as fee designated physicians under the veterans care program.

SPECIAL ORTHOPEDIC SHOES FOR VETERANS

Veterans with service connected disabilities now may obtain special orthopedic shoes free of charge from the Veterans Administration. Machines to make plaster casts of injured or deformed feet have been transferred from the War Department to the Veterans Administration and two are already in operation at the VA hospital, Hines, Ill., and the VA hospital at Atlanta, Ga., formerly the Army's Lawson General Hospital. Machines will be installed later at VA regional offices in Kansas City, Mo., New York and San Francisco. Plaster casts made by these machines will be sent to the army's quartermaster supply depot at Boston, where special lasts and patterns will be developed. The orthopedic shoes then will be constructed by commercial contractors, and completed shoes will be shipped to veterans by the VA regional office or hospital making the purchase.

Qualified veterans and also army personnel will be eligible for the service at establishments where the cast-making machines are in operation. Veterans should make applications through their nearest VA representative.

Cast-making machines are maintained by the Army at the Orthopedic Footwear Clinic, Boston, Walter Reed General Hospital, Brooke Army Medical Center, Fort Sam Houston, Texas, Fitzsimons General Hospital, Denver, and Madigan General Hospital, Fort Lewis, Washington.

PSYCHIATRISTS WANTED

Psychiatrists, clinical psychologists and psychiatric and medicosocial workers are needed by the Veterans Administration to serve in VA mental hygiene clinics now being operated in twenty-three cities. Twenty or more additional clinics in other cities are to be opened when personnel to staff them is available. Minimum qualifications for psychiatrists require certification as specialists by the American Board of Psychiatry and Neurology, or eligibility for the examination.

The grade of a psychiatrist is determined by professional qualifications, and base pay per year ranges from $4,149.60 to $10,000. Certification by the American Board of Psychiatry and Neurology entitles the psychiatrist to an additional 25 per cent of the base salary up to a limit of $11,000.

Positions for clinical psychologists and psychiatric and medicosocial workers are under the rules and regulations of the U. S. Civil Service Commission. The base pay per year ranges from $4,149.60 to $6,862.80. Applicants must have at least two years of progressively responsible experience in the application or teaching of psychologic principles and technics and proved ability to evaluate personality problems. In addition, all candidates must have completed ten required courses in the field of psychology. If an applicant has completed all requirements for a doctor's degree in psychology, he will be accepted as meeting this education requirement.

Social workers (psychiatric and medical) earn from $3,397.20 to $5,905.20 per year. One year of training in an approved school of social work is the minimum educational requirement for these positions. This training must have included supervised field work and courses in psychiatric or medical information plus the required experience, which is one year in a health or welfare agency of acceptable standards. Additional qualifying experience is required for higher grade positions. Applicants may substitute one year of training (in addition to that used to satisfy the basic requirement) completed in an approved school of social work for one year of experience.

Veterans Administration mental hygiene clinics now in operation are located at Boston, Denver, Des Moines, Iowa, St. Louis, Los Angeles, Baltimore, Pittsburgh, Chicago, Newark, N. J., New Orleans, Cleveland, Cincinnati, Detroit, Minneapolis, Portland, Ore., San Francisco, Seattle, Providence, R. I., Milwaukee, Hartford, Conn., Dallas, Texas, Philadelphia and Washington, D. C.

VETERANS' CARE IN CONNECTICUT

Connecticut's "home town" medical care plan for war veterans with service connected illnesses or injuries has been approved by the Veterans Administration. The Connecticut State Medical Society plan is now being put into action through a broad educational program among its more than 2,200 members. Main emphasis of the plan is directed toward the development of medical care for veterans in their own communities "to cultivate wholesome physician-patient relationships" and "100 per cent participation" in the plan by physicians throughout the state.

Four veteran medical officers, all members of the society, comprised the committee which developed the plan. They are Dr. Samuel B. Rentsch, chairman, of Derby, Dr. Egbert M. Andrews of Hartford and Drs. Norton Canfield and Joseph N. D'Esopo of New Haven.

MISCELLANEOUS

BANDAGES AND DRESSING FOR SALE

The War Assets Administration announces that large quantities of all types of surgical bandages and dressings which cost the government more than $1,000,000 will be offered to priority and other eligible buyers from November 20 to December 10. WAA Regional Offices at Denver, Kansas City, Mo., New York City, San Francisco and Seattle are conducting the fixed price sales. Detailed descriptions, prices and minimum purchase requirements may be obtained by writing any of the five regional offices handling the disposal.

More than 250,000 triangular compressed bandages and about 300,000 gauze bandages, some 3 inches and others 4 inches wide and all 6 yards long, are included in these sales. Large quantities of white gauze roller bandages, 4 inches by 10 yards, packed twelve rolls to a box, and of compressed bandage gauze, 3 inches by 6 yards, packed seventy-two to a box, are available at some of the five regional offices.

Orders will be accepted concurrently from all eligible buyers in the following sequence: certified veterans of World War II, Reconstruction Finance Corporation for small business, state and local governments, nonprofit institutions and nonpriority buyers. Orders received after December 10 from both priority and nonpriority buyers will be filled from remaining inventories, WAA said. Federal agencies were previously given an opportunity to fulfil their needs.

VETERANS' BABIES CARED FOR BY THE GOVERNMENT

The Children's Bureau of the Social Security Administration keeps a count of the number of servicemen's babies for whom Uncle Sam pays the stork bill, which now amounts to almost $100,000,000. The Emergency Maternity and Infant Care Program, now in its fourth year of operation, is administered by state health departments under plans approved by the U. S. Children's Bureau.

Wives and infants under 1 year of age of men in the four lowest pay grades of the Army, Navy, Coast Guard and Marine Corps are eligible, and care is given even after the serviceman's discharge, if the pregnancy occurred or the infant was under 1 year of age while the husband was in one of the eligible grades. Another hundred thousand babies are on their way, the Children's Bureau reports, and maternity care is being given to their expectant mothers. Besides, more than 180,000 of the babies already born have received or are receiving additional medical, hospital or nursing care during their first year of life.

This care is now costing Uncle Sam about $100 for a maternity case and about $65 for an infant's case. In a few cases with complications the bill runs over $1,000. The amount paid covers the cost of good maternity care, including antepartum care, delivery and care for six weeks after the baby's birth. Doctor, hospital and nurses' bills are all paid, including those for consultation and laboratory services at rates established under each state plan. Similarly, the medical and hospital bills are paid for the care of a sick baby.

"This wartime emergency measure," Dr. Martha M. Eliot, associate chief of the Children's Bureau, said, "turned out to be the largest single public medical care measure for mothers and infants so far undertaken in this country." Besides public health officials and members of their staffs who administered the state program, in one year 48,000 doctors were involved in providing care to these women and their babies. Hospitals everywhere in the country participated. "Many professional workers, motivated by a sense of public obligation, did the job," Dr. Eliot said. "Thanks are due not only the doctors, nurses and hospital staffs but also the countless individuals who took it on themselves to help out in this emergency."

The whole program, it is said, developed out of one person's efforts. Long before Pearl Harbor an army post commander, seeing the plight of many servicemen's families, sought help from the state health department. As a result a request came to the Children's Bureau asking that part of the federal funds available under the Social Security Act for maternal and child health services be used to get care to these servicemen's wives and babies. The request was granted for that state and before a year in twenty-six other states. To meet the emergency in all states Congress appropriated special funds in March 1943. Certain minimum requirements had to be met by hospitals accepting such cases under the state plans.

CANCER AND THE MEDICAL SCHOOL CURRICULUM

A special committee comprising representatives of fourteen medical schools and of the National Research Council met recently at the National Cancer Institute, Bethesda, Md., with the National Advisory Cancer Council to discuss the place of cancer in the medical school curriculum.

Dr. Frank E. Adair, chairman of the committee, declared that something must be done to improve the education of medical students in cancer, which ranks second as a cause of death in the United States. Among the suggestions made were the establishment of professorships in clinical cancer, greater use of the facilities of cancer diagnosis and cancer prevention clinics, the establishment of cancer institutes or hospitals in connection with medical schools in large urban centers, and greater emphasis in the medical school on the importance of preventive medicine.

A committee to outline a plan of teaching and to make recommendations, which will be sent to all medical schools, will be appointed later.

PERSONAL

The director, Office of Vocational Rehabilitation, Federal Security Agency, has announced the appointment of Dr. Charles L. Newberry as assistant chief medical officer succeeding Dr. Thomas B. McKneely, who was appointed chief medical officer. Dr. Newberry graduated from Marquette Medical School in 1926, engaged in private practice in Milwaukee and was associated with the city health department. On Dec. 7, 1941 he transferred to the Farm Security Administration as senior medical officer and was later commissioned in the U. S. Public Health Service and reassigned to the Farm Security Administration. In January 1945 he joined the United Nations Relief and Rehabilitation Administration as director of health in the Middle East Mission, Cairo, Egypt. Later he went to Vienna as acting chief medical officer to UNRRA in Austria. He returned to the United States in January 1946 and joined the staff of the Office of Vocational Rehabilitation.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

University News.—The Medical College of Alabama, Birmingham, announces the receipt of two grants made to Joseph K. Cline, Ph.D., associate professor of biochemistry. Distillation Products, Inc., awarded $2,500 for research in vitamin E therapy, and a grant of $7,500 by the Research Corporation for a study of antianemic substances was made this month. In studying the antianemic substances he will work with substances that stimulate the regeneration of red blood cells and will attempt to determine the mechanism of their actions. Dr. Cline, formerly director of the laboratory of the nutrition clinic at the Hillman Hospital, was appointed to the faculty of the medical college in March. Dr. Joseph F. A. McManus has been appointed assistant professor of pathology at the Medical College of Alabama. Dr. McManus served in the Royal Canadian Army Medical Corps from September 1940 to 1945; he joined the Medical College of Alabama after doing research in histochemistry at the University Museum, Oxford, England. Clarence E. Klapper, Ph.D., and his wife, Margaret Strange Klapper, have been appointed assistant professor in anatomy and instructor in the department of medicine, respectively.

CALIFORNIA

Personal.—Dr. Willis L. Jacobus Jr. has been appointed athletic medical director of the University of Southern California, Los Angeles. He succeeds Dr. Packard Thurber Jr., who resigned after holding the position for twenty-one years to devote all his time to general practice.

Position Available.—The Los Angeles Psychiatric Service, an adult community mental hygiene clinic supported by the Community Chest, has an opening for a psychiatrist-director to give full time to the clinic. The requirements are that the director be a specialist certified in psychiatry and have some administrative experience. The clinic personnel includes volunteer psychiatrists, two psychiatric social workers and a psychologist. The salary is in accordance with qualifications. Address the Los Angeles Psychiatric Service, 507 South Westlake Avenue, Los Angeles 5.

CONNECTICUT

New Medical Director of Welfare Department.—Dr. Philip W. Fenney of West Haven has been appointed medical director of the Connecticut State Welfare Department. The appointment of Dr. Fenney, a veteran of World War II, is on a temporary basis with examination for the position to be held later, according to the statement of Commissioner Robert H. Smith. Dr. Fenney succeeds Dr. Leonard Parente, who resigned last month after four years with the department, to become health officer of Hamden.

Centennial Meeting of Hartford Medical Society.—As part of the observance of the one hundredth anniversary of its founding in 1846, contemporary members of the society reenacted an early meeting of the Hartford County Medical Society on September 16 at the Hunt Memorial Building, 38 Prospect Street, Hartford. The program closed with a dinner meeting and address by President G. Keith Funston of Trinity College on "Liberal Education and Its Relation to Medicine." Each member present received a copy of the historical volume published for the occasion and entitled "The First Century of the Hartford Medical Society."

Liaison Committee on Occupational Health.—The governing council of the Connecticut State Medical Society has appointed a liaison committee to the new Institute of Occupational Medicine and Hygiene at Yale University, New Haven. Members of the new committee are Dr. Thomas P. Murdock, Meriden, council chairman; Dr. Creighton Barker, New Haven, executive secretary, and Dr. Charles F. Yeager, Bridgeport, chairman of the society's committee on industrial health. The institute will be headed by Dr. Ronald F. Buchan, West Hartford, recently appointed assistant professor of industrial medicine, who will serve as the clinical director (The Journal, November 9, p. 591).

GEORGIA

Joint Meeting.—Dr. Frank H. Lahey, Boston, was among the speakers October 1 at a meeting which was the first annual session of the Georgia chapter of the American College of Surgeons and the fall meeting of the Fifth District Medical Society. The session, held in Atlanta, also included clinics. Dr. Lahey discussed "The Management of Lesions of the Stomach, Duodenum and Jejunum."

ILLINOIS

Personal.—The town of Kempton held a community dinner in the local high school November 3 to honor Dr. William G. Ross on his seventy-seventh birthday. Dr. Ross, who has practiced in Kempton for forty-three years, was presented with a radio.

Chicago

Walter Theobald Heads Medical Center Commission.—Dr. Walter H. Theobald on November 20 became chairman of the Medical Center Commission, succeeding Dr. Raymond B. Allen, who resigned to become president of the University of Washington.

Lecture by British Biochemist.—Dr. Douglas Robertson, professor of biochemistry, Middlesex Hospital Medical School, London, lectured at the University of Illinois College of Medicine November 8 on "The Nature of the Disturbed Calcium and Phosphorus Excretion in Thyrotoxicosis and Myxedema."

Charles Swift Retires.—Dr. Charles H. Swift, associate professor and secretary of the department of anatomy at the University of Chicago School of Medicine, has been retired with emeritus status, it was announced November 26. Dr. Swift, who has reached the university's automatic retirement age, has been associated with the university for the past forty-seven years; he graduated at Rush Medical College in 1910.

The Ranson Lecture.—Dr. Albert M. Snell, chief of the section on medicine, Mayo Clinic, Rochester, Minn., and professor of medicine in the Mayo Foundation, delivered the annual Stephen Walter Ranson Lecture, sponsored by the Phi Beta Pi Fraternity, at Northwestern University Medical School on Tuesday, December 3. The lecture was presented at Thorne Hall, on the Chicago campus of Northwestern University, at 5 p. m. Dr. Snell's subject was "Recent Advances in the Field of Hepatic and Biliary Disease."

Herman Smith Resigns at Michael Reese.—Dr. Herman Smith has resigned as executive director of Michael Reese Hospital to become a hospital consultant on a full time basis in Chicago. He leaves Michael Reese after twenty-six years' service. Dr. Morris H. Kreeger, assistant director of Mount Sinai Hospital, New York City, from 1940 to 1946, arrived at Michael Reese November 18 to take over the executive directorship of the hospital. Dr. Kreeger graduated at Jefferson Medical College in Philadelphia in 1935 with prizes in surgery, neurology and ophthalmology and was in general practice in Bloomfield, N. J., from 1937 to 1939.

INDIANA

Students Win Awards.—The Osterman awards of the Indiana University School of Medicine, Indianapolis, have been announced as follows:

First prize, $20, John Edward Ross, Experimental Hemothorax.
$15 prizes: Don G. Buck, Lesions of the Spinal Epidural Space Producing Cord Compression.
Charles E. Buck, The Bleeding Nipple.
Gilbert B. Causey, Early Diagnosis and Management of Small Intestinal Obstruction.
Charles C. Gullet, Vagotomy for Gastroduodenal Ulcer.
Paul William Holtzman, Regional Enteritis.
John W. Mason, Jaundice, Surgical Considerations.
Roy V. Maxson, Traumatic Rupture of the Spleen.
$10 prizes: Davis A. Baltz, Congenital Cystic Lung. Pneumonectomy in a 3 Week Old Baby.
Robert P. Buckler, The Immersion Foot Syndrome.
Robert D. Cunningham, Causalgic States in Peace and War.
John H. Grant, Studies in Experimental Vascular Surgery.
George T. Lukemeyer, Shock and Refrigeration.
$5 prizes: John W. Geddes, Management of Abdominal Wounds in Warfare.
Oscar Green, Thrombophlebitis, Experience at an Army General Hospital.
August M. Kasper Jr., Refrigeration Anesthesia.
Theodore R. LeMaster, A Review of Posttraumatic Renal Injury.
John R. Porter, A Study of Shock in Battle Casualties.

The Osterman Prizes were established by Mr. H. Osterman, Seymour, in 1939 for outstanding papers by students in the medical school (The Journal, Nov. 25, 1939, p. 2011). The recipients are chosen by the editorial board of the *Quarterly Bulletin*, published by the medical school.

MARYLAND

New Radiology Department at Johns Hopkins.—Dr. Russell H. Morgan, former associate professor of radiology at the University of Chicago, has been made professor of radiology in the Johns Hopkins University School of Medicine and radiologist in chief at the Johns Hopkins Hospital, effective about January 1. Dr. Morgan will be in charge of a new department of radiology created at the university and the hospital. Radiology, formerly a section in the division of surgery, has been made an independent department of the two Hopkins institutions in order to provide better clinical service at the hospital, to improve instruction in the university and to promote research in this increasingly important field.

MASSACHUSETTS

Personal.—Dr. Abraham Cohen, Philadelphia, and Dr. Loring T. Swaim, Boston, were guest speakers at the recent convention of the International Society of Medical Hydrology at Buxton, England, on "Treatment of Arthritis."——Dr. Henry D. Chadwick, Cambridge, state health commissioner of Massachusetts from 1933 to 1938, retired recently as medical director and superintendent of the Cambridge Sanatorium, a position he had held since 1942.——Albert H. Hegnauer, Ph.D., Syracuse, N. Y., and Dwight J. Mulford, Ph.D., Boston, have been appointed associate professor of physiology and assistant professor of pharmacology, respectively, at Boston University School of Medicine.

MISSOURI

Personal.—On September 4 Andrew H. Panetiere Post number 490 honored Dr. Edwin C. White, Kansas City, particularly in gratitude for the news letter which he edited and which was sent to the members of the Jackson County Medical Society, including those who were in service.

Faculty Changes.—Recent faculty changes in the St. Louis University School of Medicine include the following: Dr. Percy J. Carroll (brigadier general, U. S. Army, retired), assistant dean and professor of public health; Dr. Mark C. Wheelock, assistant professor of pathology, and Dr. Paul A. Murphy, assistant professor of pharmacology.

Lawyer Appointed to Health Post.—On August 31 Samuel Marsh, a lawyer of Kansas City, was named by Governor Donnelly as director of public health and welfare. The appointment is subject to confirmation by the senate. As director of the department of public health and welfare Mr. Marsh is administrative head of three divisions, public health, mental diseases and welfare. According to the Kansas City *Star* his office will manage the state hospitals and the social security program in Missouri.

NEW YORK

Cancer Teaching Day.—On December 12 a Cancer Teaching Day will be presented in Troy under the auspices of the Medical Society of the County of Rensselaer, Tumor Clinic Association of the State of New York, the state medical society and the New York State Department of Health Division of Cancer Control. The speakers will include:

Dr. Hayes Martin, New York City, Mouth Cancer.
Dr. Cushman D. Haagensen, New York City, Tumors of the Breast.
Dr. Louis C. Kress, Buffalo, Tumors of the Bone.
Dr. Richard B. Cattell, Boston, Malignant Tumors.
Dr Harold W. Dargeon, New York City, Tumors in Children.

New York City

The Brickner Lecture.—The Hospital for Joint Diseases announces that the 1946 Walter M. Brickner Lecture will be delivered by Dr. Arnold R. Rich, professor of pathology at the Johns Hopkins University School of Medicine, Baltimore, December 12, at the hospital. The subject is "Problems Relating to the Pathogenesis of Cirrhosis of the Liver."

Consulting Pneumatologist Named for Hospital.—Dr. Paluel J. Flagg was appointed consulting pneumatologist to the Manhattan Eye, Ear and Throat Hospital November 21. The action was taken by the board of directors of the hospital at the recommendation of the board of surgical directors. The action was said to stem from a resolution passed by the House of Delegates of the American Medical Association, December 4, 1945.

Julius Jarcho Honored.—Dr. Julius Jarcho was guest of honor at a dinner November 21 to mark his retirement as president of the medical board of Sydenham Hospital. A feature of the occasion was the dedication of the library of the hospital to him and named the Dr. Julius Jarcho Library. Dr. Jarcho has been associated with Sydenham Hospital for the past forty years and served as president of the medical board during the latter ten years. He is attending surgeon in obstetrics and gynecology at Sydenham and is the author of several textbooks and treatises on obstetrics and gynecology which are used in medical teaching. Dr. Jarcho graduated at Columbia University College of Physicians and Surgeons in 1904.

Erythroblastosis Fetalis Clinic.—The Jewish Memorial Hospital has established a clinic for the study and treatment of erythroblastosis fetalis under the direction of Dr. Harry Wallerstein, hematologist to the hospital, in collaboration with Drs. Milton J. Goodfriend, attending obstetrician, Michael Schuman, attending pediatrician, Alfred Angrist, director of laboratories, and Philip Levine, consulting serologist. The clinic solicits specimens for study from cases presenting implications of erythroblastosis fetalis. In suitable cases mothers will be accepted for admission to the antepartum clinic and/or delivery. Babies born outside this institution in whom the suspicion of erythroblastosis exists will also be accepted for admission. Further information will be obtained from the superintendent of the Jewish Memorial Hospital.

Portrait of Dr. Rowland G. Freeman.—On November 20 a portrait was unveiled of Dr. Rowland G. Freeman at the New York University College of Medicine. The portrait, a gift to the college by Dr. Rowland G. Freeman, son of the late Dr. Freeman, was painted by the artist William J. Whittemore, an intimate friend of the late Dr. Freeman. Dr. Freeman developed methods of studying the bacteria in milk. He with other members of the college faculty organized a milk commission supervising certified milk production in New York City. Dr. Freeman was the first secretary of the commission. He was also chairman at the time of his death on Nov. 14, 1945, a position he held for twenty-eight years. Dr. Freeman graduated at Columbia University College of Physicians and Surgeons. He joined the New York University faculty in 1898 as chief of the pediatric clinic. He was made professor of pediatrics in 1920, becoming emeritus with his retirement in 1930.

Grant-in-Aid for Tropical Medicine.—The department of preventive medicine, New York University College of Medicine, has received a grant-in-aid from the American Foundation for Tropical Medicine to assist in establishing a unit for the development of tropical medicine and parasitology in connection with Bellevue Hospital. The unit will consist of a clinician, Dr. Harry Most, a parasitologist, Donald V. Moore, Ph.D., and a technician. A diagnostic laboratory will be set up in connection with the third (New York University) division of Bellevue Hospital for the examination of blood and fecal specimens. The laboratory will also serve other divisions of the hospital as examinations are requested. It will also furnish teaching material for medical students. Dr. Most and Dr. Moore will act as consultants to the clinical staff and will conduct the teaching program in tropical medicine and parasitic diseases in the medical school. Dr. Most has been on leave of absence for service in the army. He has been in charge of the tropical medicine section of Moore General Hospital, Swannanoa, N. C. Dr. Moore comes to the department from the State Health Department of Texas, where he has been in charge of the parasitology division of the state laboratory.

NORTH CAROLINA

Medical Lectures.—The Matheson Foundation Medical Lectures, sponsored by the Matheson Foundation and the Mecklenburg County Medical Society, was held in Charlotte at the Hotel Charlotte, October 31-November 1. Among the speakers were:

Dr. Henry L. Bockus, Philadelphia, Clinical Aspects of Infectious Hepatitis.
Dr. Donald G. Anderson, Boston, The Treatment of Infections with Penicillin and Streptomycin.
Dr. Isidor S. Ravdin, Philadelphia, Some Problems in Biliary Tract Surgery.
Dr. Edward A. Schumann, Philadelphia, Obstetric Hemorrhage.
Drs. Cyrus C. Sturgis and Carl V. Weller, Ann Arbor, Clinicopathologic Conference.
Dr. Francis E. McDonough, Boston, The Diagnosis and Medical Management of Lesions of the Stomach, Duodenum and Jejunum.
Dr. Frank H. Lahey, Boston, The Surgical Management of Lesions of the Stomach, Duodenum and Jejunum.

OHIO

Research on Coronary Occlusion.—Under two grants totaling $7,000 from the U. S. Public Health Service Dr. Roy W. Scott, professor of clinical medicine, Western Reserve University School of Medicine, and his associates at University and City hospitals in Cleveland, will administer carefully controlled doses of Dicumarol (3-3'-methylene-bis-[hydroxycoumarin]) to men and women hospitalized after attacks of coronary occlusion. In announcing the project Dr. Scott said he was encouraged to carry on the work as a result of a few reports in the medical literature indicating that Dicumarol may appreciably lower the death rate from heart disease by preventing the clots from blocking the circulation in other parts of the body. As president of the American Heart Association last year Dr. Scott appointed a committee to direct a cooperative study of Dicumarol by several institutions. For this study the U. S. Public Health Service has contributed a total of $35,000. At University Hospitals the program is being conducted by Dr. Joseph M. Hayman Jr., professor of clinical medicine and therapeutics at Western Reserve, and Dr. Harold Feil, associate clinical professor of medicine.

OKLAHOMA

Changes in Health Officers.—Included among recent appointments to the Oklahoma State Department of Health are those of Drs. George W. Winn, Lawton, county superintendent of health of Comanche County; James M. Gordon, Ardmore, county superintendent of health of Carter County; William W. Cotton, Atoka, county superintendent of health of Atoka County, and Alfred R. Sugg, Ada, county superintendent of health of Pontotoc County.

PENNSYLVANIA

Philadelphia

Personal.—Dr. Abraham Cohen was recently a guest speaker at the convention of the International Society of Medical Hydrology in Buxton, England, on the "Treatment of Arthritis."——Dr. William P. Bager Jr., medical director and internist, St. Luke's Hospital, Bluefield, W. Va., has been appointed associate medical director of Sharp and Dohme.

Penicillin or Silver Nitrate in Ophthalmia Neonatorum.—On November 7 a resolution was presented to the Eye Section of the Philadelphia County Medical Society requesting the appointment of three members, one an ophthalmologist, one a gynecologist and one a bacteriologist, to constitute a committee known as the Committee on the Prevention of Ophthalmia Neonatorum. The resolution urged that this committee undertake a study with the view of determining whether silver nitrate may be abandoned altogether and whether penicillin would be more effective in the treatment of the expectant mother and as a preventive agent in the eyes of the newborn. The resolution points out that the action should be taken because penicillin is universally recognized as a bacteriostatic agent possessing chemotherapeutic properties against the gonococcus and other organisms; silver nitrate has been used since 1884 as a chemical to prevent ophthalmia neonatorum caused by the gonococcus and other organisms; ophthalmia neonatorum has not been completely eliminated despite the use of silver nitrate; silver nitrate in 1 and 2 per cent solutions may cause a chemical conjunctivitis; the prevention of ophthalmia neonatorum is concerned primarily with the prevention of gonorrhea in the expectant mother, and gonorrhea may be treated and cured in the expectant mother with the use of penicillin.

Pittsburgh

The Huggins Memorial Lecture.—On November 22 Dr. Paul R. Cannon, chairman, department of pathology, University of Chicago School of Medicine, lectured on "Clinical Approach to the Problem of Protein Deficiency Disease." The lecture was given at the University of Pittsburgh School of Medicine under the auspices of chapter Nu of the Phi Delta Epsilon Fraternity.

VERMONT

State Health Council Created.—On November 15 the Vermont state health council was organized to coordinate health programs in the state. Representatives of twenty-nine Vermont organizations participated in the initial meeting. The meeting was sponsored by the Vermont State Medical Society. The constitution of the new council embodies many of the principles of the governor's twenty-two point health program. According to the Rutland *Herald*, November 16, the object of the new group is revision and expansion of the state public health department, "integration" of public health department and college of medicine laboratories, establishment of small rural health centers, expansion of nutrition programs, control and eradication of tuberculosis, venereal diseases, undulant fever and other communicable diseases, also diagnosis, care and treatment for other diseases and increased maternal health services, child health service expansion to include medical and dental examinations and immunization, and extension of treatment and care of the mentally ill and mentally deficient. Other programs outlined included support of the college of medicine at the University of Vermont, promotion of hospital development, efforts to make the practice of medicine in rural areas more attractive, correct pay inequalities for health and hospital personnel, promotion of the education, training and welfare of the nursing and the pharmaceutical professions and the supporting of legislation to the ends outlined. Dr. Frank C. Angell, Randolph, president of the Vermont State Medical society, was elected chairman. Other officers include Howard Reid, D.D.S., Vermont State Dental association, vice chairman, Mr. John W. Brownlee, executive secretary, Vermont State Medical society, secretary, and Stanley G. Judd, commissioner of agriculture, treasurer.

WEST VIRGINIA

Approved New Cancer Center.—At a meeting of the executive committee of the West Virginia Cancer Society, Inc., October 31, at Clarksburg Mr. Homer Gebhart of Huntington, treasurer of the society, was named disbursing agent for all county and local cancer organizations. The establishment of a cancer information center, with a cancer field worker recommended by the project committee, was unanimously approved. The committee directed that, of the 60 per cent of funds realized from cancer drives which will remain in this state, 15 per cent is to be utilized for administrative expenses at the state offices. The remaining 45 per cent may be expended as follows: An approved project in any county may spend up to 45 per cent of that county's annual contribution. If the full 45 per cent is not sufficient to finance the approved project, the executive committee can appropriate from the state general fund a sufficient amount to take care of the balance, and an adjoining or adjacent county to an approved project may allocate its entire 45 per cent to that project. The preliminary report of the project committee, submitted by Dr. Paul R. Gerhardt, chairman, and Drs. Thomas L. Harris and Richard O. Rogers and approved by the executive committee, provides that all local projects must have the approval of the cancer committee of the local medical society. The committee unanimously disapproved the affiliation of county cancer organizations with community chest drives.

Hospital Survey.—The sum of $22,500 has been allocated by Governor Clarence W. Meadows from his emergency fund to cover the state share of the cost of a statewide hospital survey, which will be made under the provisions of the recently enacted Hill-Burton bill whereby Congress appropriated $75,000,000 a year for five years for the construction of hospitals, medical centers and clinics throughout the country. West Virginia's share is $1,555,000 per year. This state will receive $11,250 from the federal government to help finance the survey which is required under the provision of the bill. The survey will be under the immediate supervision of Dr. Newman H. Dyer, state health commissioner. Dr. Paul R. Gerhardt, director of the division of cancer control, will serve as consultant and medical adviser. Much of the preliminary work has already been completed by Mrs. George Fordham, a member of the state health department's administrative staff. It is expected that the budget, which was prepared and mailed to Washington early in November, will be approved without delay, and it is hoped that the survey may be completed within the next four to five months. An advisory committee is to be appointed by the governor which must approve any report that is submitted to Washington for consideration by the U. S. Public Health Service. The bill provides for the construction of hospitals, clinics and medical centers by states, counties, municipalities and nonprofit organizations.

WISCONSIN

Helmholz Lecture.—Sir Lionel E. H. Whitby, C.V.O., M.C., M.A., M.D. Cantab., F.R.C.P. Lond., D.P.H., currently regius professor of physic, department of medicine, University of Cambridge, and honorary consulting hematologist to the Royal Army Medical Corps, delivered the A. C. Helmholz Lecture before the faculty and students at the school of medicine, University of Wisconsin, November 19. The subject of the lecture was "Hematologic Effects of Radiation."

Annual Preceptors Meeting.—On November 22-23 the University of Wisconsin Medical School resumed its annual scientific meeting for the associated teaching staff of preceptors. The preceptorial staff consists of physicians in various localities throughout the state and carries out a part of the extramural teaching of senior medical students. Each fourth year medical student spends twelve weeks with one of the preceptorial groups. This is made possible by making the fourth year of the medical course twelve months in length rather than nine months. The program was arranged by the faculty of medicine in Madison and took place in the auditorium of the Service Memorial Institute building of the medical school and in the wards of the State of Wisconsin General Hospital. The program included:

Paul F. Clark, Ph.D., Oswald S. Orth, Ph.D., and Dr. Ovid O. Meyer, Symposium on the Antibiotics.
Dr. Sture A. M. Johnson, Cutaneous Manifestations of Some Common Medical Conditions.
Dr. Edgar S. Gordon, The Management of Some Difficult Metabolic Problems.
Dr. Daniel Murray Angevine, Fatal Pulmonary Embolism.
Dr. William D. Stovall, Hemolytic Reactions, Transfusions and Erythroblastosis.
Dr. Warren E. Gilson, Electronics in Research and Clinical Medicine.
Drs. Helen A. Dickie and Joseph W. Gale, Current Medical and Surgical Aspects of Tuberculosis.
Dr. William S. Middleton, Some Medical Aspects of World War II.

GENERAL

Congress on Obstetrics and Gynecology.—The American Congress on Obstetrics and Gynecology will be held in the Municipal Auditorium in St. Louis, Sept. 8-12, 1947. The second congress was held in the same place in 1942 and the first congress in Cleveland in 1939. Dr. Fred L. Adair, Chicago, is again general chairman.

Fellowship in Medicine.—The American College of Physicians offers a limited number of research fellowships, designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine, pediatrics and other allied fields. Assurance must be provided that the applicant will be acceptable, and the laboratory will supply the facilities necessary for the proper pursuit of the research. The term of appointment is for one year, usually beginning on July 1. The stipend will be from $1,800 to $3,000 a year. Application forms will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, and must be submitted in duplicate, with a recent photograph of the applicant. It is desirable that applications be filed by December 1 each year. Awards will be made on or about January 1. Dr. Reginald Fitz, Boston, is chairman of the committee on fellowships and awards.

Southern Surgical Association.—The fifty-eighth annual session of the Southern Surgical Association, Hot Springs, Va., will be held December 10-12 under the presidency of Dr. Daniel C. Elkin, Atlanta, Ga. Included among the speakers are:

Dr. Winchell McK. Craig, Rochester, Present Status of the Surgical Treatment of Hypertension.
Drs. Elmer C. Bartels and Frank H. Laney, Boston, Use of Thiouracil, Thiobarbital and Propyl Thiouracil in Patients with Hyperthyroidism.
Dr. Richard W. Te Linde, Baltimore, Surgical Treatment of Urinary Incontinence in Women.
Dr. Guy W. Horsley, Richmond, Va., Treatment of Cancer of the Breast in Premenopausal Patients with Radical Amputation and Bilateral Oophorectomy.
Drs. Willard H. Parsons, Vicksburg, Miss., and John S. Harter, Louisville, Ky., Pulmonary Resection for Gangrene of the Lung.
Dr. Frank P. Strickler, Louisville, Ky., True Cavernous Hemangioma of the Uterus.

At the association dinner Wednesday evening Dr. Elkin gave his address entitled "The Georgia Blister and Critic" and Francis Pendleton Gaines, LL.D., president, Washington and Lee University, Lexington, Va., spoke on "Lee: Leader of an Educational Renaissance."

"The Challenge of the Future."—The National Society for Crippled Children and Adults will hold its silver anniversary convention at the Palmer House, December 9-11. The theme of the convention will be "The Challenge of the Future." Among the speakers will be:

Dr. Waldo E. Nelson, Philadelphia, Convalescent Care for the Handicapped.
Dr. Arthur C. Bachmeyer, Chicago, Developments in Hospital Planning of Interest to Workers for the Handicapped.
Dr. Morris Fishbein, Editor, The Journal, The Medical Care Program of the American Medical Association.
Dr. Alfred R. Shands Jr., Wilmington, Rehabilitation in General Hospitalization.

One general session Wednesday morning, December 11, will be devoted to consideration of the care of the children with cerebral palsy with the following speakers:

Mr. Lawrence J. Linck, Chicago, A National Cerebral Palsy Program.
Jayne Shover, Chicago, Cerebral Palsy Across the Nation.
Dr. Winthrop M. Phelps, Cockeysville, Md., Treatment of Cerebral Palsy.
Dr. Temple S. Fay, Philadelphia, Causal Aspects of Cerebral Palsy.
Dr. Leslie B. Hohman, Baltimore, Assuring Social Acceptance of Cerebral Palsied Children.
Dr. Earl R. Carlson, Pompano Beach, Fla., Educational Needs of the Cerebral Palsied Child.
Dr. Meyer A. Perlstein, Chicago, Recent Advances in Drug Therapy for Cerebral Palsy.
Participation by parents of cerebral palsied children, "As I See It."

Mead Johnson & Company B Complex Award.—Nominations are solicited for the 1947 award of $1,000 established by Mead Johnson and Company to promote researches dealing with the B complex vitamins. The recipient of this award will be chosen by a committee of judges of the American Institute of Nutrition, and the formal presentation will be made at the annual meeting of the institute, May 18-22, 1947. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who, in the opinion of the judges, has published during the previous calendar year, January 1 to December 31, the most meritorious scientific report dealing with the field of the B complex vitamins. While the award will be given primarily for publication of specific papers, the judges are given considerable latitude in the exercise of their function. If in their judgment circumstances and justice so dictate, it may be recommended that the prize be divided between two or more persons. It may also be recommended that the award be made to a worker for valuable contributions over an extended period but not necessarily representative of a given year. Membership in the American Institute of Nutrition is not a requisite of eligibility for the award. To be considered by the committee of judges, nominations for this award for work published in 1946 must be in the hands of the chairman of the nominating committee by Jan. 15, 1947. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate the task of the committee of judges in its consideration of the nomination. The chairman is Robert R. Sealock, Ph.D., Department of Chemistry, Iowa State College, Ames, Iowa.

Merck Fellowships in Natural Sciences.—Merck & Co. has established a group of fellowships in natural sciences to be administered by the National Research Council. Not to exceed ten in number, the fellowships are to assist young men and women who have demonstrated ability in research in the chemical and biologic sciences. The fellowships will provide advanced training in these fields. They are open to citizens of the United States who have already acquired the training in chemistry or biology represented by the degree of Ph.D. or its equivalent. The initial appointment will be for a term of one year, renewable for a second, and in exceptional cases for a third. Fellows will be encouraged to undertake their fellowship work in institutions other than those in which their original training has been obtained. The amount of the annual stipend, which will be in the range of $2,500 to $5,000, will be determined by individual circumstances. An allowance for necessary travel will be available in addition. An amount of $500 or more will be provided annually for the institutional expenses of each successful candidate. Applications for Merck Fellowships should be filed by Jan. 15, 1947. Decisions concerning awards will be made as soon as practicable after March 1, 1947. The fellowships will become effective on July 1, 1947. Address communications to the Merck Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. Members of the Merck Fellowship Board are:

Alfred N. Richards, Ph.D., chairman, University of Pennsylvania School of Medicine.
George W. Beadle, Ph.D., California Institute of Technology.
Hans T. Clarke, D.Sc., Columbia University College of Physicians and Surgeons, New York.
George O. Curme Jr., Sc.D., Carbide and Carbon Chemicals Corporation, New York.
René J. Dubos, Sc.D., Rockefeller Institute for Medical Research, New York.
The chairman, National Research Council, Washington, D. C., ex officio.

Marriages

Wallace C. Ward, Raleigh, N. C., to Miss LaRene Slater of New Orleans and Apalachicola, Fla., at Charlotte, N. C., August 8.

Raymond Crawford Ramage, Jacksonville, Fla., to Miss Marguerite G. Taylor in Morristown, Tenn., August 24.

Robert N. Brown, Altadena, Calif., to Miss Rosalie Rumsey of Potterville, Mich., in Glendale, Calif., in September.

Edmund Rhett Taylor, Rochester, Minn., to Miss Mary Baldwin Herbert of Columbia, S. C., September 6.

Dale Quinn Furnell, St. Paul, to Miss Phyllis Lovaun Jacobson of St. James, Minn., June 15.

Edward Henderson McGehee to Miss Carolyn Dunn, both of Mobile, Ala., September 10.

Charles Richard Yoder to Miss Edith King, both of Chicago, September 14.

Deaths

Howard Merrill Clute ⊕ Brookline, Mass.; Dartmouth Medical School, Hanover, N. H., 1914; born in North Berwick, Maine, January 10, 1890; served as professor of surgery at the Boston University School of Medicine; secretary of the Section on Surgery, General and Abdominal, American Medical Association, from 1932 to 1935, when he was elected chairman; member of the American Surgical Association, Southern Surgical Association, American Society for the Study of Goitre and the Société Internationale de Chirurgie; member and past president of the Boston Surgical Society; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; for many years associated with the Lahey Clinic; served as chief of the surgical service at Carney Hospital in South Boston; for many years chief of the surgical service at Massachusetts Memorial Hospitals, where, in recognition of his administrative ability, he was elected to the board of trustees; on the staffs of the Burbank Hospital in Fitchburg, Mass., New England Baptist and New England Deaconess hospitals in Boston; served in the medical corps of the U. S. Army during World War I and was honorably discharged with the rank of major; received the honorary degree of doctor of science from Dartmouth in 1941; died suddenly September 19, aged 56, of coronary thrombosis.

David A. Stanton, High Point, N. C.; Vanderbilt University School of Medicine, Nashville, 1887; born in Level Cross, N. C., May 24, 1859; member of the American Medical Association; honorary member, formerly vice president and secretary of the Medical Society of the State of North Carolina; past president and first secretary of the Guilford County Medical Society; fellow of the American College of Surgeons; served as resident surgeon of the Southern Railway, city health officer, medical director of the Colonial Life Insurance Company, mayor of High Point, member of the board of nursing examiners and state board of health; for many years chairman and treasurer of the city school board; served as city councilman; a charter member of the Perpetual Building and Loan Association, founded in 1901, which he served as first vice president and retired as president to become a member of the board of directors; director of the Pickett Cotton Mills; vice president of the High Point Savings and Trust Company; served on the staffs of the Guilford General Hospital and the High Point Memorial Hospital; died September 5, aged 87, of cardiovascular renal disease.

Sidney Samuel Weinstein, Denver; University of Tennessee College of Medicine, Memphis, 1929; member of the American Medical Association; served as an instructor of pediatrics at the University of Colorado School of Medicine; specialist certified by the American Board of Pediatrics; served on the staffs of the Children's, Beth Israel, Colorado General and Denver General hospitals; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve in October 1942; service terminated Jan. 30, 1946; died September 12, aged 41, of coronary thrombosis.

Oliver Goldsmith Tinkham ⊕ Boston; Tufts College Medical School, Boston, 1905; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; served as instructor in surgery at his alma mater; on the staffs of the Massachusetts Woman's Hospital, Boston, Newton (Mass.) Hospital and Symmes Arlington Hospital, Arlington; on the associate staff of the New England Baptist Hospital, Boston, and Cambridge Hospital, Cambridge; surgeon, Boston Dispensary and Boston Floating Hospital; died September 10, aged 67, of carcinoma.

Henry Wellington Banks, Norwood, Pa.; Medico-Chirurgical College of Philadelphia, 1902; member of the American Medical Association; died September 24, aged 71.

Eugene Fogle Beard, Somerset, Ky.; University of Louisville Medical Department, 1911; member of the American Medical Association; served during World War I; surgeon for the Southern Railway; died September 19, aged 64, of heart disease.

George Gernon Bergeron ⊕ Ludlow, Mass.; Temple University School of Medicine, Philadelphia, 1917; served in France during World War I; school physician; died September 26, aged 55, of carcinoma of the lung.

Alick Bernstein, Chicago; University of Illinois College of Medicine, Chicago, 1916; member of the American Medical Association; died April 4, aged 52.

Leonard Rudolph Boen, Bauxite, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; died at Clarksville September 11, aged 63.

Harry Rich Bolan, Cambridge, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1915; died September 25, aged 63, of hypertensive heart disease.

Edward Jesse Burnett, Los Angeles; Kansas City (Mo) Medical College, 1903; died July 18, aged 67.

James Roderick Butler, Mountain City, Tenn. (licensed in Tennessee in 1912); member of the American Medical Association; served as mayor of Mountain City and as county health officer; died September 28, aged 57, of carcinoma.

L. D. Carter, West Liberty, Ky.; Kentucky School of Medicine, Louisville, 1882; died in Lexington September 24, aged 92.

Jediah Hussey Clark, Winter Park, Fla.; Medical College of Indiana, Indianapolis, 1895; past president of the Fayette-Franklin Counties (Ind.) Medical Society; served as secretary of the board of health of Connersville, Ind.; killed in an automobile accident near Macon, Ga., September 22, aged 77.

Bernard L. Cleary, Edgerton, Wis.; Rush Medical College, Chicago, 1900; died in the Edgerton Memorial Hospital September 21, aged 76, of carcinoma of the bladder and prostate

Joseph Wilmer Cox, Groesbeck, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1893; fellow of the American College of Surgeons; chief examiner, Limestone County Selective Service Board; medical director and owner of Dr. Cox's Hospital; died September 17, aged 78, of bronchopneumonia.

George S. Cressman, Pughtown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the American Medical Association; died September 26, aged 77, of Parkinson's disease.

William Ray Day, Fairfield, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1901; died September 19, aged 80, of leukemia.

Louis Sharpe Dunaway, Jr. ⊕ Conway, Ark.; University of Arkansas School of Medicine, Little Rock, 1929; served as a captain in the medical corps, Army of the United States, during World War II; died September 18, aged 46, of lymphosarcoma.

Welcome McClellan Elwell, Toledo, Ohio; Starling Medical College, Columbus, 1890; died September 29, aged 82, of cerebral hemorrhage.

Ernest Emory Esley, Walworth, N. Y.; Cleveland Homeopathic Medical College, 1902; member of the American Medical Association; served as health officer and fire commissioner; associate staff member of the Genesee Hospital in Rochester, where he died September 28, aged 76, of arteriosclerotic heart disease.

Albert S. Faulkner, Waynetown, Ind.; University of Louisville (Ky.) Medical Department, 1893; member of the American Medical Association; died September 25, aged 76, of cerebral hemorrhage.

Frank M. Gaines, Verden, Okla.; Kentucky School of Medicine, Louisville, 1894; died in August, aged 86.

Albert William Glathar ⊕ Pueblo, Colo.; University of Nebraska College of Medicine, Omaha, 1929; diplomate of the National Board of Medical Examiners; past president and secretary of the Pueblo County Medical Society; on the staffs of the Parkview Hospital and St. Mary's Hospital, where he died September 27, aged 45, of mycosis.

Frederick George Graves ⊕ Bethlehem, Conn.; Yale University School of Medicine, New Haven, 1892; past president of the Connecticut State Medical Society; died September 23, aged 77.

Harry Gus Greditzer, St. Louis; Washington University School of Medicine, St. Louis, 1912; member of the American Medical Association; on the staff of the Jewish Hospital; died September 27, aged 56, of coronary occlusion.

Charles Michael Hauslein, Omaha; Rush Medical College, Chicago, 1900; died in the Immanuel Hospital September 8, aged 73, of heart disease.

William Herbert Ingram, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1894; served as professor of pathology, bacteriology and histology at his alma mater, now known as the University of Pittsburgh School of Medicine; died July 4, aged 77, of cerebral hemorrhage.

Lawrence Leslie Irwin, Bloomington, Ill.; St. Louis University School of Medicine, 1907; member of the American Medical Association; on the staff of St. Joseph's Hospital, where he died September 17, aged 60, of cerebral hemorrhage.

Harry Breckenridge Jacobson, Dallas, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1918; member of the American Medical Association; died in Gaston Hospital August 31, aged 54, of congestive heart disease.

Maurice Kemp ⊕ Allentown, Pa.; Cornell University Medical College, New York, 1907; past president of the Lehigh Valley Medical Society; served during World War I and as examining physician for the induction center during World War II; died September 24, aged 60.

Clarence Perry Kummer ⊕ Buffalo; University of Buffalo School of Medicine, 1917; served during World Wars I and II; member of the American Heart Association; on the staff of the Deaconess Hospital; died September 16, aged 52, of coronary occlusion.

William Leonard, Fostoria, Ohio; Western Reserve University Medical Department, Cleveland, 1888; served during World War I; died September 23, aged 84, of heart disease.

Harold L. Lorentzen, Petaluma, Calif.; Hahnemann Hospital College, San Francisco, 1900; College of Physicians and Surgeons of San Francisco, 1902; died in a hospital at Santa Rosa September 6, aged 81, of bronchopneumonia, Parkinson's disease and arteriosclerosis.

Frank Mansfield Loring, Howard, S. D.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; died September 6, aged 85.

S. J. McGraw, El Dorado, Ark.; University of Arkansas School of Medicine, Little Rock, 1906; member of the American Medical Association; served as city and county health officer; died in the Warner Brown Hospital September 6, aged 72, of coronary thrombosis.

James Alexander MacKenzie, Boston; Tufts College Medical School, Boston, 1913; died September 16, aged 68, of heart disease.

George Ralph Maner ⊕ Tampa, Fla.; University of Georgia Medical Department, Augusta, 1893; on the courtesy staff of the Tampa Municipal Hospital; died July 23, aged 74, of coronary occlusion.

Harrie Breckinbridge Martin, Springfield, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1903; for many years affiliated with the Springfield City Hospital; died September 1, aged 68, of heart disease.

Patrick Joseph O'Dea, Fitchburg, Mass., University of Vermont College of Medicine, Burlington, 1912; member of the American Medical Association; died September 25, aged 59, of coronary sclerosis.

Frederick E. Pierce, Chicago; National Medical College, Chicago, 1897; served on the school board and city council of Earlville, Ill.; died September 27, aged 85.

Robert Pierson Regester, Philadelphia; Jefferson Medical College of Philadelphia, 1916; died in the U. S. Naval Hospital June 8, aged 54, of hypertensive cardiovascular disease.

Thomas McPherson Roberts, Sweetwater, Tenn.; Kentucky School of Medicine, Louisville, 1894; member of the American Medical Association; died in the Sweetwater Hospital September 14, aged 77, of carcinoma of the liver.

Henry Joseph Rock, Wilmington, Del.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; member of the House of Delegates of the American Medical Association in 1904, 1907 and 1908; served as mayor of Aberdeen, S. D., where he was on the staff of St. Luke's Hospital; died September 9, aged 82, of cerebral hemorrhage.

Bertha May Satterlee, Bellevue, Ohio; Cleveland Medical College, 1894; died September 2, aged 78.

George Louis Schneider ⊕ Williamsport, Pa.; Jefferson Medical College of Philadelphia, 1911; fellow of the American College of Surgeons; past president of the Lycoming County Medical Society; served as county coroner; on the staff of the Williamsport Hospital, where he died September 17, aged 60, of coronary thrombosis.

Ralph Levi Souder, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1896; died July 23, aged 74, of cerebral hemorrhage.

Trond Neilson Stabo ⊕ Decorah, Iowa; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1894; died in Hayward, Wis., August 20, aged 76, of heart disease.

Allison A. Stamm, Mohnton, Pa.; University of Vermont College of Medicine, Burlington, 1883; member of the American Medical Association; died July 21, aged 90, of arteriosclerosis.

Oscar Blue Swayze, Auburn, N. Y.; Long Island College Hospital, Brooklyn, 1892; member of the American Medical Association; served on the staffs of the Mercy and Auburn City hospitals; died September 4, aged 82, of arteriosclerosis.

William Joshua Groot Thomas, Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1908; served during World War I; on the staffs of the Sibley Hospital and the Garfield Memorial Hospital, where he died September 22, aged 71, of cerebral thrombosis and diabetes mellitus.

Payne Alexander Tinsley, Dandridge, Tenn.; University of Louisville (Ky.) Medical Department, 1895; died September 5, aged 80, of heart disease.

Henry B. Trigg, Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1904; member of the American Medical Association; at one time on the faculty of his alma mater; died in a local hospital September 12, aged 66.

Karl William Wahlberg ⊕ Moline, Ill.; Rush Medical College, Chicago, 1912; past president of the Rock Island County Medical Society; past president and vice president of the Iowa and Illinois Central District Medical Society; served during World War I; on the staffs of the Moline Public and Lutheran hospitals; died September 29, aged 59, of myocardial infarction.

Armon French Wicks, Okolona, Miss.; College of Physicians and Surgeons, Memphis, Tenn., 1911; awarded the Purple Heart and Silver Star for service overseas during World War I; died in Memphis, Tenn., September 19, aged 66.

Benjamin A. Wilkes, North Hollywood, Calif.; Hospital College of Medicine, Louisville, 1882; served as president of the American Protestant Hospital Association; formerly superintendent of the Missouri Baptist Hospital in St. Louis and the Southeast Missouri Hospital in Cape Girardeau, Mo.; served as superintendent of the Hollywood Clara Barton Memorial Hospital in Los Angeles; died September 18, aged 88.

Ernest G. Wilson ⊕ Kankakee, Ill.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; served on the staff of St. Mary Hospital; died September 25, aged 61, of coronary thrombosis.

Frederick Newton Winans, Franklin, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1874; member of the American Medical Association; life member of the Otsego County Medical Society; for many years served as health officer, president of the board of trustees of the Delaware Literary Institute and as village president; honorary member of the staff of the Sidney (N. Y.) Hospital; died September 21, aged 95, of senility.

Charles Henry Wyatt ⊕ Kansas City, Mo.; University of Arkansas School of Medicine, Little Rock, 1931; interned at the Kansas City General Hospital, where he was a member of the staff; served on the staff of the Research Hospital, where he died September 15, aged 42, of acute hemorrhagic pancreatitis.

KILLED IN ACTION

Capt. Joseph C. Bulfamonte
M. C., A. U. S., 1907-1946

Joseph Charles Bulfamonte ⊕ Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1932; interned at the Philadelphia General Hospital; served a residency at the Norristown State Hospital in Norristown, Pa., and the Ashland State Hospital in Ashland, Pa.; served on the staff of the Shamokin (Pa.) Hospital; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army on April 19, 1941; later promoted to captain in the medical corps, Army of the United States; prisoner of war in the Philippine Islands; presumed dead March 14, 1946, aged 39.

Nov. 15, 1946.

Sanitary Condition of France

The present minister for public health is the last provisory minister of the present government of France. The poll of the 10th of November will establish for five years a new parliament and a long term government. The minister in a statement on his activity during this short period, read at a press conference, gave some insight on the sanitary condition of the country. He had to direct his efforts toward the solution of numerous urgent problems. A census of the hospital appliances has been taken and a scheme of reequipment, giving priority to war devastated "Départements" has been established. Reconstruction work has began at Nantes and Toulon; at Lorient and Brest the hospital system has been reestablished; at Rouen, Rennes, Rheims and Nancy the U. S. Army has given the hospitals back to the civil sanitary services. The second examination of the deported and prisoners having shown an increase in cases of tuberculosis, several new sanatoriums, among which is one in the Black Forest, in the French occupation zone, have been opened and numerous radiology cars have been bought. The working of the sanitary control at the frontiers has been reinforced and a sanitary team is in action at the Marseilles-Marignane air port; similar ones are being organized at Le Bourget and Orly. The first 600,000 sanitary books to be used for newborn children have been distributed. The circular of the 3d of September has created a section of sanitary education in each district. Penicillin, which, up to the present moment, was used only in special centers, is now available for every doctor. The Information Bulletin of the Ministry for Public Health contains a favorable statement of the epidemic condition of France last summer: Apart from the poliomyelitis epidemic, which is declining, two localized epidemics of typhoid and paratyphoid and some cases of Weil's disease have been reported.

Special circulars have ordered the reorganization of the psychiatric equipment and of the antituberculosis organizations. Laws concerning the protection of mothers and children have been promulgated and are in course of realization. The weak points, pointed out by the minister, are a delay in the modernization of equipment in hospital appliances, due to the war and Nazi occupation, and backwardness in the field of anesthesia, due to the impossibility of taking part in international congresses.

Several missions for study have been sent to the United States, Great Britain and Russia. There is a shortage of certificated nurses and district nurses; also a lack of cars for doctors and especially for country doctors; in order to make up for it army cars will be allotted to them. In order to avoid the parallelism of the activities of the Ministries for Public Health and of Social Security in the planning of the organization of the hospital system, an interministerial commission of coordination has been appointed. In the organization of the sanitary service, decentralization will be maintained: in each city of more than 20,000 inhabitants a municipal bureau of hygiene will be created and the power of the mayor, as regards public hygiene and sanitary police, will be increased. In every center of more than 10,000 inhabitants the establishment of "goutte de lait" (the drop of milk) organization for the supervision and the repartition of wholesome milk is foreseen as well as, in each department, the creation of a committee for the protection of unadopted children. A detailed plan for departmental public schools for nurses and district nurses is also completed and will be presented to the future parliament. The creation of sanitary "attachés" to the embassies in China, the United States and Russia are foreseen for 1947.

OSLO

(From a Special Correspondent)

Nov. 11, 1946.

Airplane Flights for Whooping Cough

The somewhat bizarre treatment of the intractable cough of whooping cough patients by sending them for a spin in an airplane does not seem to be remarkably successful. Inquiries recently addressed to the mothers of these patients sent aloft at the Fornebu airdrome near Oslo yielded the information that in 9 out of 33 cases improvement was noted from two to fourteen days after the flight. In most cases no improvement was effected, and all the parents achieved was the expenditure of 60 to 90 kroner for the flights and the exposure of their children to the risks incidental to flying. Dr. Alf Ödegaard, who has collected these data by interviewing the parents, has found little reason for recommending this treatment as a safe and rational procedure.

Diabetes Mellitus in Bergen

Dr. Per Hanssen of the staff of Ullevaal Hospital has published a study of diabetes in Bergen, the population of which is about 100,000. The object was to investigate the morbidity, age at onset, duration and the most frequent complications of diabetes, as well as the causes of death since the introduction of insulin treatment. He finds that, since the introduction of this treatment, it has become increasingly necessary to distinguish between deaths from diabetes and deaths from other causes in diabetic patients. To this end he suggests that in the future a distinction should be made between the two in the official notifications of death. The observations of Joslin and his fellow workers are made by Dr. Hanssen to serve as a background for his own investigations, which in more than one instance show that the behavior of diabetes is by no means the same in different countries.

The Shock Treatment of Psychoses in Norway

Dr. H. H. Dedichen, in charge of the private asylum associated with his name near Oslo, has completed a study of the shock treatment of psychoses as practiced in various Norwegian asylums. This 160 page study, issued by the Danish publisher Ejnar Munksgaard in 1946, covers a period of several years and deals with material collected in seventeen different asylums. In the autumn of 1938 Dr. Dedichen enlisted the cooperation of the medical superintendents of these asylums, many of which have also provided valuable control material. Altogether, 1,459 shock treated patients were compared with 969 comparable patients not given such treatment. Throughout this study Dr. Dedichen shows himself acutely conscious of the many pitfalls awaiting any one undertaking such a comparison, and he has taken special pains in matching the psychoses of the treated and not treated patients. One of his important conclusions is that the benefits of shock treatment are greatest and most effectively demonstrable when the duration of the mental disease in question has been less than one year before the institution of this treatment.

Heredopathia Atactica Polyneuritiformis

Dr. Sigvald Refsum, on the staff of the Neurologic University Clinic in Oslo, has published a comprehensive study of a familial syndrome which has not hitherto been described. This syndrome appeared in two Norwegian families not related to each other and living in two widely separated districts in Norway. Hemeralopia was observed in all 5 patients and atypical retinitis pigmentosa in 3 members of one family. In 2 members of the other family there were reasons to suspect this condition or a similar condition without pigmentation. Other characteristics of the syndrome were suggestive of chronic polyneuritis and ataxia. There were also certain other cerebellar phenomena.

IMPORTANCE OF BLOOD GROUP TESTS

To the Editor:—In the October 19 issue of THE JOURNAL an editorial comment stressed the value of blood tests for identification, especially in relation to blood samples and stains obtainable at postmortem examination. The article urged that "provision should be made to collect and save samples of blood at necropsies for eventual blood group tests much more regularly than is now the usual practice."

I should like to suggest another important place for complete blood grouping as a means of identification where mistaken identity has often caused much anguish and has even made history, namely in the delivery room. Nowadays most hospitals take prints of the mother's thumb and of the newborn infant's foot as a means of identification. Usually either or both prints are smudged beyond recognition and are worthless. Even if the prints are taken carefully, they soon become useless because the baby's foot pattern, unlike that of an older child, or adult, changes after a few months and cannot be duplicated.

Employing blood groups in identification of the newborn child would be far more useful because they are permanent and can always be duplicated. Furthermore, the blood sample can be obtained from the umbilical cord, thus identifying the child even before it leaves the mother's side for its first bassinet. This sample of blood, oxalated, in a corked tube of suitable size, can easily be fastened to the mother's body, thus preventing separation of the baby's means of identification from its mother during her transfer to her postpartum bed.

With the six blood groups and subgroups (O, A_1, A_2, B, A_1B and A_2B), the three MN types (M, N and MN), the agglutinogen P (P+ and P—) and the ten Rh-Hr types, 360 varieties of human blood can be differentiated. Surely, the chance of incorrectly identifying a baby in this way is far smaller than by means of a smudgy footprint which could not be duplicated in the event that the identity of the child should be questioned a few months after birth.

Admittedly, identification of babies through the medium of blood groups demands reasonable knowledge of grouping tests and of the use of the various testing serums, but, since such knowledge can be obtained and since all the necessary serums are becoming more readily available, there is no great or insurmountable obstacle in the path of its development.

MALCOLM A. HYMAN, M.D.,
Blood Transfusion Service,
Jewish Hospital of Brooklyn,
Brooklyn.

PENICILLIN INHALATION

To the Editor:—Reading the report on Penicillin Inhalation by Morse in THE JOURNAL October 5 and the editorial in the same issue on Penicillin Aerosol Therapy prompted me to suggest that a review of the literature on this subject would have provided a more dependable guide for the dosage, technic and results of the use of penicillin by inhalation.

Morse's observations on 25 patients with various types of upper respiratory complications seen during an influenza epidemic unfortunately lack evidence to support the statement that the dosage required by this method is less than that needed by intramuscular injections for the management of pulmonary infection. He employed a hand bulb nebulizer technic which produces coarse sprays, probably deposited largely in the oropharynx, trachea or larger bronchi. Small doses totaling 14,000 to 80,000 units of penicillin were given daily in four divided doses for two to four days. He stated "I have always used 4 drachms (15 cc.) in twenty-four hours." Referring to his most concentrated dilution, this would mean about 16,000 units in 4 cc. of solution for each treatment. This would require considerable hand pumping during an allotted ten minute period! Certainly such a technic is hardly feasible for a sick patient. This small dosage might possibly be valuable in the variety of milder respiratory complaints in his patients but would be entirely inadequate and dangerous for the control of the types of bronchopulmonary infections best managed by penicillin aerosol therapy.

Effective penicillin aerosol therapy can provide good topical effect as well as adequate blood levels. In 118 determinations I obtained blood levels which ranged from 0.015 to 0.225 unit per cubic centimeter with doses of 25,000 to 50,000 units. My studies and those by Barach and Olsen have repeatedly indicated the need for adequate doses, ranging from 200,000 to 500,000 units daily, for the satisfactory control of most bronchopulmonary infections. The saving in penicillin should not be used as an argument for employing this method.

The administration of penicillin by inhalation for respiratory infections is more than empirical therapy. A number of patients with lung abscess, bronchiectasis and nonpneumococcic pneumonias had received intramuscular penicillin and oral sulfonamides without demonstrated improvement before getting penicillin aerosol which resulted in cure. However, it does have a limited field of usefulness and should be employed only when definitely indicated and then with an effective technic. Such therapy is mainly indicated for patients having purulent sinusitis, bronchiectasis and lung abscess, especially in the presence of streptococcus, staphylococcus, pneumococcus or penicillin-susceptible strains of Friedländer's infections of the lungs and acute infectious laryngotracheobronchitis. In chronic bronchitis, bronchial asthma and pulmonary emphysema penicillin aerosol may or may not be preferable to systemic penicillin administration but it has been found equally beneficial. Every attempt should be made to identify the organisms from the nose, throat and sputum and, if possible, to determine the penicillin sensitivity before instituting adequate therapy.

MAURICE S. SEGAL, M.D., Boston.

Medical Motion Pictures

FILM REVIEW

Vaginal Flora During Pregnancy. 16 mm., color, silent, 790 feet, showing time twenty-two minutes (run at sound speed). Prepared in 1946 and procurable from A. Herbert Marbach, M.D., 1022 Medical Arts Building, Philadelphia.

A motion picture showing normal and abnormal flora during pregnancy with associated p_H changes. Gross changes of the vagina are also illustrated. An elaborate scientific film based on vaginal cultures made through a sterile tube introduced in the vagina, through which is passed a swab used for the culture.

This picture requires considerable knowledge of bacteriology. Parts, such as the preparation of the hands in order to make these cultures, are overdone. The film requires additional explanatory titles in order that the average physician may fully appreciate its practical value. The type of audience recommended includes gynecologists, medical students, interns and residents.

The film possesses educational value and should be repeatedly shown to establish knowledge of the complicated bacterial flora of the vagina.

The color photography is well done.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment.]

Asthma Tea.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially roughly ground plant material, identity not reported. Misbranded because label falsely represented product as efficacious in preventing, curing or treating asthma, and because label misstated quantity of contents.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Balm and Gilead Herb Tonic.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942 Composition: plant drug extractives (no alkaloids), a small amount of gum resin, reducing sugar, and water. Misbranded because labeling falsely represented it as helpful for asthma cough and chronic cough, and as a tonic for these conditions.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Brom-Acet.—Purity Drug Company, Inc., New York. Shipped June 18 and 23 and July 11, 1942. Composition: from 10.4 to 11.9 grains of sodium bromide per ounce, whereas label claimed 16 grains of this substance per ounce. Hence adulterated and misbranded.—[*D. D. N. J., F. D. C. 1022; March 1945.*]

Blood and Liver Capsules. — Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: mercury (about 10 per cent) and black pepper reported. Misbranded because falsely represented to remedy disorders of blood, liver, stomach and bowels.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Blood Tonic.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: plant debris (not identified), water-soluble plant extractives, and water, with a foul odor suggesting burdock or Jimson weed. Misbranded because title falsely represented article as a tonic—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Cel-Bio Mineral Tablets. — Cel-Bio Mineral Food Company, Omaha. Shipped May 7 and 8, 1942. Composition of all tablets, numbered from 1 to 12, essentially lactose with a minute amount of a different mineral in each. All misbranded because of label misrepresentations as to their effects on various disorders.—[*D. D. N. J., F. D. C. 1042; March 1945.*]

Codecol.—Harvey Laboratories, Inc., Philadelphia. Shipped Sept. 22 and Dec. 12, 1942. Composition: not more than 6.73 grains of ammonium chloride or 0.1 grain of antimony potassium tartrate per fluid ounce, whereas falsely represented to contain larger amounts, and hence adulterated and misbranded.—[*D. D. N. J., F. D. C. 1017; March 1945.*]

Colusa Natural Oil, Colusa Natural Oil Capsules and Colusa Natural Oil Hemorrhoid Ointment.—Colusa Products Company, Berkeley, Calif. Shipped Jan. 31, 1941. Composition: the two first-named products consisted of crude petroleum oil, containing 0.75 per cent of sulfur, but not the camphor, turpentine, iodine or iodine compounds declared on label. Ointment was essentially zinc oxide, crude petroleum oil and small amounts of camphor, menthol and benzocaine in a base of lanolin and beeswax. Oil and Capsules misbranded because label falsely represented them as efficacious in treating eczema, psoriasis, acne, ringworm, athlete's foot, poison ivy, varicose ulcers and some other conditions; Ointment misbranded because label falsely represented it as efficacious in treating hemorrhoids.—[*D. D. N. J., F. D. C. 1040; March 1945.*]

"For Nervous Run Down Women."—A product of this name was sold by the Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially a small amount of plant debris (type not reported), water-soluble plant extractives and water. Misbranded because name falsely represented that the product would benefit nervous, rundown conditions in women.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Hart's Vitamin B Elixir.—E. J. Hart & Company, Ltd., New Orleans. Shipped June 8, 1942. Adulterated and misbranded because product contained only 13.8 milligrams of nicotinic acid per fluid ounce instead of the 20 milligrams falsely declared on label.—[*D. D. N. J., F. D. C. 1029; March 1945.*] Also declared adulterated and misbranded under the provisions of the law applicable to foods, as reported in *F. N. J. 5775.*

Kaps Colloidal Iodized Sulphur.—Jamco Company, New York. Shipped June 5 and Aug. 27, 1942. Composition: capsules containing mineral oil, sugar, small amounts of sulfur, and an iodide. Misbranded because label statement, "For use as an aid in the relief of arthritis due to sulphur deficiency," falsely represented product as effective for arthritis. —[*D. D. N. J., F. D. C. 1046; March 1945.*]

Manning's Asthma Plaster. — Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially dry ground mustard and ground black pepper. Misbranded because name falsely suggested usefulness for asthma.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Manning (D. R.) Antiseptic Douche Powder.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially 4 parts of boric acid to 1 of oxyquinoline sulfate. Misbranded because falsely represented that when diluted according to directions it was an antiseptic and efficacious as a douche for feminine hygiene.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Manning (D. R.) Asthma Salve.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially petrolatum, with a small amount of volatile oils, including menthol, eucalyptol and camphor. Misbranded because falsely represented on label as efficacious for head colds, headache, catarrh, hay fever, asthma and sinus disorders.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Manning (D. R.) Throat Gargle.—Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially plant material, probably of citrus and pineapple origin, and water, preserved with sodium benzoate. Misbranded because label falsely represented that product was an adequate treatment for sore, inflamed or hoarse throat and would remove goiter.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Manning's Princess Gaynell Hair Tonic. — Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: a small amount of plant debris, with odor of cardamom or lavender. Misbranded because label falsely represented that product was a food or fertilizer for the hair, would feed the roots and act as a tonic for the hair.—[D. D. N. J., *F. D. C. 1043; March 1945.*]

Nakamo Bell Tablets. — Hollings-Smith Company, Orangeburg, N. Y. Shipped Nov. 20, 1942. Composition: in each tablet essentially 2 grains of ammonium chloride, 3 grains of sodium chloride and 1 grain of potassium chloride. Misbranded because label falsely represented efficacy of product in treating hay fever, sinusitis, asthma and colds.—[*D. D. N. J., F. D. C. 1045; March 1945.*]

Pantabee. — Charles C. Haskell & Company, Inc., Richmond, Va. Shipped Jan. 13, 1943. Composition: not more than 250 International units of vitamin B_1 per capsule, whereas strength was given as 333 International units on label. Hence adulterated and misbranded.—[*D. D. N. J., F. D. C. 1027; March 1945.*] Also adulterated and misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 5774.*

Py-Ro.—Oran Products, New York. Shipped April 3, 1943. Composition: essentially sodium hypochlorite, chlorthymol, and oil of peppermint dissolved in water. Misbranded because name and label suggestions falsely represented the product as an effective treatment for pyorrhea and trench mouth.—[*D. D. N. J., F. D. C. 1089; April 1945.*]

Rheumatox.—Rheumatox Company, Cleveland. Shipped April 20 and July 15, 1942. Composition: essentially an aqueous solution of sodium salicylate, methenamine, potassium citrate, potassium iodide, emodin-bearing drugs, and a small amount of alcohol. Misbranded because name of product and firm would give erroneous impression that Rheumatox would cure, prevent or mitigate rheumatism; because label falsely represented that excess uric acid commonly causes arthritis, neuritis, lumbago, sciatica, rheumatic pains and gout, and that Rheumatox would prevent or cure these conditions, and because label failed to declare presence of potassium iodide, an active ingredient.—[*D. D. N. J., F. D. C. 1044; March 1945.*]

Sun-Glow Cod Liver Oil Concentrate Tablets.—Brewer & Company, Inc., Worcester, Mass Shipped July 15, 1941. Misbranded because labeling misstated content of vitamins A and D and falsely represented product as efficacious in preventing and treating disease by increasing general resistance, toning the system and developing strong bones and good teeth. —[*D. D. N. J., F. D. C. 1013; March 1945.*] Also adulterated and misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 6597.*

Swiftide Brand Cod Liver Oil.—Swiftide Company, Portland, Maine. Shipped Feb. 7 and April 4, 1942. Adulterated and misbranded because quality fell below standard set for cod liver oil by the United States Pharmacopeia.—[*D. D. N. J., F. D. C. 1015; March 1945.*]

Vigor 8.—Royal Products Company, Chicago. Shipped March 23, 1944. Composition: dried brewers' yeast, corn flour, and corn and wheat germs. Misbranded because labels, as well as "Charles D. Kasher's Health and Beauty Chart" which accompanied product, falsely represented that article was of significant nutritional value in that it contained factors of brewers' yeast, and the elements potassium, sulfur, sodium, magnesium, copper, zinc, chlorine and manganese, and that use of Vigor 8 would prevent or correct many disorders, such as cold infection, ulceration, stone formation, cystitis, paralysis, cataract, scurvy and diabetes.—[*D. D. N. J., F. D. C. 1078; April 1945.*] Also declared misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 6591.*

Whoa Liniment. — Manning Herb House, Bessemer, Ala. Shipped March 30, 1942. Composition: essentially an inflammable hydrocarbon capable of ignition with red hot metal, and containing mustard oil and camphor. Misbranded because falsely represented as an adequate treatment for arthritis, lumbago, sciatica and kindred disorders.—[*D. D. N. J., F. D. C. 1043; March 1945.*]

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Failure to Remove Gauze Packing From Antrum.—The plaintiff sought to recover damages for the loss of an eye, alleged to have been caused by the defendant's failure to remove a piece of gauze packing from the plaintiff's antrum for approximately five months after a surgical operation. The jury returned a verdict of $20,000, it being specified that $10,000 was "for loss of sight of her eye." The court entered judgment for the plaintiff for $10,000, it being of the opinion that there was no evidence that the alleged negligence was the proximate cause of the loss of the eye. Both parties appealed to the Supreme Court of Oregon.

In July 1940 the plaintiff consulted the defendant, a surgeon of some thirty-five years' experience, relative to a growth or cyst on the inside of her nose which x-ray pictures showed to be a tumor of the antrum. Surgery was recommended and an operation performed in October 1940. During the operation a specimen of tissue was submitted to Dr. Robertson, a pathologist, and his report showed that the plaintiff had a basal cell type of cancer—i. e., a low grade cancer which had invaded the bone or roof of the antrum. The cancer was removed and, in view of the pathologic report, the operation was more extensive than had been anticipated, it being necessary to remove much of the channel bone between the antrum and the nose and some of the bone constituting the roof of the antrum, which is also the floor of the orbital cavity. The defendant testified in effect that, since the cancerous cells were ascending in the bone of the antrum, he removed some of the bone but did not go into the orbital cavity on account of the serious consequences to the eye and cheek bone. Later it was decided to use radium to kill the remainder of the cancer cells. Defendant admitted having used gauze packing in the operation but asserted positively that it was removed when the operation was completed. He was corroborated in this respect by other witnesses who assisted him.

Subsequently Dr. Wight, a specialist in radium therapy, inserted a 0.50 milligram radium capsule in plaintiff's antrum and left it there for a period of forty-eight hours. Dr. Wight testified that, when this treatment was completed, the capsule and gauze packing surrounding the same were removed in the presence of the defendant and that the antrum was then free of any gauze packing. Dr. Wight explained the nature of radium therapy and stated that its rays would kill not only cancer cells but also other cells and tissue within a certain radius. It was his opinion that the radium treatment would not only damage the bone of the orbital cavity but would probably result in the loss of the eye. The testimony shows that cancer of the antrum is rare and the rate of mortality in such cases is extremely high. Therefore it is fair to assume that the defendant and his assistants were primarily concerned with curing the cancer, since, if the cancer was not cured, the loss of the eye would be of secondary importance. For the few months following the radium treatment the plaintiff was in and out of the hospital, her condition becoming progressively worse. The antrum was irrigated and treated by x-ray. The eye was in a serious condition at this time, necrosis of the bone having progressed rapidly, and there was a profusion of foul pus. The defendant said that he may have used gauze packing during this period of treatment to aid in drainage of the pus.

After leaving the hospital, plaintiff called regularly at the office of Dr. Fenton, an eye, ear, nose and throat specialist, for treatment of her eye. On March 1 Dr. Fenton looked into the antrum, which is about the size of a large walnut, "to see whether there were any fragments of bone which might be loose" as a result of the radium treatment and then discovered a piece of gauze packing ½ inch wide and 4 or 5 inches long. It was "wadded up pretty solid, because it was packed in there tight" and was covered with pus having a "terrible odor." The defendant had not informed him about the gauze packing and he was very much surprised to find it. The plaintiff desired the piece of gauze to show Dr. Pettit but "Dr. Fenton very properly ordered it destroyed." Plaintiff said that, after the gauze was removed, she was able to breathe again through the left nostril. Dr. Fenton, in response to a hypothetical question, testified that it was not proper practice thus to leave a piece of gauze packing in the operative area for a period of five months "or thereabouts." On March 5 Dr. Fenton removed plaintiff's left eye. He said that at that time "there was no cancer, it had all been killed." It was his opinion that the loss of the eye was caused by the radium and not by the infection resulting from the gauze packing. This conclusion as to the cause of the loss of the eye was supported by all the other medical experts, with the exception of one who testified on behalf of the plaintiff.

The only expert witness who testified on behalf of the plaintiff was a Dr. Nelson, who examined the plaintiff in the latter part of March in order to qualify as an expert witness. He testified, among other things, "I don't believe there ever was a cancer there" and that he did not believe in radium or x-ray therapy for treatment of cancer, although he confessed to never having used the same in his practice. On direct examination, in response to a hypothetical question, Dr. Nelson stated positively that the gauze packing was the cause of the loss of the eye and that radium had nothing to do with it. On cross examination, however, he testified, in answer to a question as to what damage would the radium do, "Well it would destroy the eye in that condition—in that place."

Has it been established with reasonable certainty that leaving the gauze packing in the plaintiff's antrum was the cause of the loss of her eye, the Supreme Court asked, or was such damage caused by the radium treatment? The evidence viewed in the light most favorable to plaintiff is that the loss of the eye might, with equal probability, be caused by either the gauze or the radium. The testimony of Dr. Nelson concedes that such is true and the evidence on behalf of the defendant is that the gauze had nothing whatever to do with such damage. Under that state of the record the jury was left only to speculate as to that phase of the case. The Supreme Court therefore concluded that the plaintiff was not entitled to the award of $10,000 for loss of the eye and that the trial court was right in eliminating such sum from the judgment. Accordingly the judgment in favor of the plaintiff for $10,000 was affirmed.—*Parker v. Pettit, 138 P. (2d) 592 (Ore., 1943)*

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Nov. 30, page 810.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Part II.* Dec. 16-17. *Part III.* Boston, Chicago, Jan. 9-11. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* Los Angeles, 2d week in April. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written. Oral.* Chicago, Feb. 12-14. Final date for filing application is Jan. 1, 1947. March 17. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY. Examination to be given during the Summer. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral. All Groups. Parts I and II.* Dec. 1. Chicago. [illegible] date for filing application is March 1. Sec., Dr. S. J. [illegible], Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* St. Louis, Dec. 15 and April 16-19. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

72:137-250 (Aug.) 1946

Estivoautumnal (Plasmodium Falciparum) Malaria: Survey of 493 Cases of Infection with Plasmodium Falciparum in Children. N. H. Einhorn and W. J. Tomlinson.—p. 137.
*Clinical Ascariasis: Analysis of 202 Cases. J. C. Swartzwelder.—p. 172.
*Human Infections with Salmonella Panama. R. H. High and E. H. Spaulding.—p. 181.
Causes of Prematurity: VIII. Influence of Infections, Chronic Disorders and Accidents on Incidence of Prematurity. Estelle W. Brown, R. A. Lyon and Nina A. Anderson.—p. 189.

Clinical Ascariasis.—Swartzwelder states that of 11,000 stools of clinic and hospitalized patients at the Charity Hospital in New Orleans examined by his associates and himself 426 were found to contain ova of Ascaris lumbricoides. He presents an analysis of the clinical and laboratory data from the case records of 202 persons with clinically evident A. lumbricoides infection admitted to the Charity Hospital of Louisiana during a period of about a decade. The age of 170 patients was under 16 years and of 15 patients over 30. The most common symptoms were abdominal pain or discomfort, passing of ascarids by the anus, the mouth or the nose, vomiting, abdominal or epigastric tenderness, fever, constipation, abdominal distention, cough or cold, nausea, headache and diarrhea. Convulsions, abnormal pulmonary conditions, anorexia, loss of weight, weakness, malaise, restlessness, abdominal rigidity, palpable abdominal masses, dyspepsia and dyspnea ranked next in order of frequency. Abdominal pain was frequently sudden in onset and recurrent in nature. In 18 cases the diagnosis was intestinal obstruction due to A. lumbricoides. In 16 cases the obstruction occurred prior to anthelmintic treatment. In 2 cases the obstruction occurred following treatment with santonin or with carbon tetrachloride. In both cases the termination was fatal. No posttreatment obstruction resulted in any of the cases treated with hexylresorcinol or with oil of chenopodium U. S. P. Six cases of intestinal obstruction were fatal. The most frequent tentative diagnoses included intestinal parasites (helminthiases), ascaris infection, chronic recurrent appendicitis, infection of the upper respiratory tract, gastroenteritis, tuberculosis, intestinal obstruction, subacute appendicitis, epilepsy, intussusception and intestinal intoxication. In over half of the cases in which differential leukocyte counts were done there was an eosinophil count of less than 3 per cent. The maximum eosinophil count was 28 per cent.

Human Infections with Salmonella Panama.—High and Spaulding report 3 cases of human Salmonella panama infections and suggest that S. panama is not primarily an animal pathogen, which is the generally accepted view, but essentially a human parasite. The first of the 3 cases was one of mild gastroenteritis in an adult; the second, one of meningitis successfully treated with sulfadiazine in an infant; the third, one of fatal Salmonella septicemia in a newborn infant. S. panama should be considered as primarily a "human" type of Salmonella the transmission of which is predominantly from man to man rather than from animal to man.

Isolation of Virulent Treponema Pallidum from Human Aorta Thirty-Two Hours After Death from Cardiovascular Syphilis. C. K. Hu, Y. Liu, K. C. Chen and C. N. Frazier.—p. 301.

Anticonvulsant Properties of Tridione.—Tridione has been made available as a symptomatic therapy for petit mal epilepsy. Goodman and his associates compared the anticonvulsant properties of tridione in animals with those of diphenylhydantoin and phenobarbital by six different laboratory technics. Of all the results obtained, the antagonism to metrazol is the property which most sharply distinguishes tridione from both diphenylhydantoin and phenobarbital. Of particular significance in relation to the known specificity of tridione against petit mal is its ability to abolish the petit mal-like electroencephalographic dysrhythmia produced in animals by metrazol. On the basis of electroencephalographic and clinical study of a selected group of patients with slow wave dysrhythmias, recommendations have been advanced for the clinical use of tridione alone or in combination with other drugs. A sharp rise in seizure rate may be observed in petit mal patients during the first twenty-four hours of tridione therapy. This transient exacerbation is not a contraindication to the drug and may be followed by complete clinical remission. Although freedom from seizures may continue for weeks after discontinuation of tridione, withdrawal should not be attempted until the patient has been seizure free for many months. Abrupt cessation of tridione medication does not entail the danger of "status epilepticus." Drug treatment for associated grand mal should not be stopped when tridione therapy for petit mal is initiated. If psychomotor electroencephalographic dysrhythmia is associated with a petit mal history, diphenylhydantoin combined with tridione is probably the treatment of choice. An occasional patient may respond well to tridione alone. Preliminary electroencephalographic examination provides a sounder basis than clinical history of seizure type for deciding whether tridione should be used alone or in combination with other agents.

Total Pancreatectomy.—Ricketts and his associates report physiologic and metabolic studies on a man who had undergone pancreatectomy, the completeness of which was established at necropsy. The pancreatectomy was done for carcinoma when the patient was already diabetic and had chronic diarrhea. The stomach, duodenum, spleen and left adrenal also were removed. For approximately three months the patient remained in sufficiently good condition to permit metabolic studies. Loss of the pancreas led to an increase in diarrhea, even though the patient was receiving powdered pancreas in large amounts. Intestinal absorption of both fat and protein, already less than normal before operation, was strikingly diminished thereafter. The large loss of nitrogen in the feces was accompanied with a relatively low urinary loss. Analyses of food and excreta showed a slightly positive calcium and phosphorus balance, despite the severe diarrhea. Extirpation of the pancreas was not followed by any increase in the requirement for insulin, which, with a diet containing 400 Gm. of carbohydrate, averaged about 40 units per day. Sensitivity to insulin was great, the patient experiencing frequent hypoglycemic reactions. When the patient was maintained on three injections of crystalline insulin per day, the last dose being given before supper, the fasting blood sugars were essentially normal. This is contrary to the usual finding in severe, spontaneous diabetes. Also at variance with the behavior of such patients was the response in the present case to intravenously administered glucose, the resultant blood sugar curves being less "diabetic" than might be expected. The authors think that the considerable loss of nutriment through diarrhea may explain certain apparent differences between the diabetes in this case and the spontaneous disease of ordinary diabetic patients.

Intracranial Epidermoids (Cholesteatomas). W. A. Bennett.—p. 588.

Fibrous Dysplasia of Maxilla and Mandible.—Schlumberger reports 12 cases of fibrous dysplasia (so-called ossifying fibroma) of the maxilla and the mandible in members of the army whose average age was 26 years. Only 1 patient, a 15 year old boy, was a civilian dependent. The maxilla was involved seven times and the mandible four times in the 11 cases of this series in which the bone lesion was solitary. In the single polyostotic case the mandible was the only bone of the skull affected. Curettement or attempted excision of the lesion was the only therapy employed in these cases. Biopsy revealed partially calcified trabeculae of bone arising by direct metaplasia within a connective tissue stroma; these were indistinguishable in their structure and arrangement from fibrous dysplasia occurring in other bones, e. g. the ribs. The arrangement of the new bone in the form of spherules and the presence of nonossified deposits of calcium were frequently observed in these cases but were also found in lesions of the ribs and long bones in cases with a definite diagnosis of fibrous dysplasia reported by other authors. Since microscopic criteria do not exist by which fibrous dysplasia of the maxilla or mandible can be distinguished from so-called ossifying fibroma of these bones and because their clinical behavior is identical, it is concluded that the ossifying fibroma is a variant of monostotic fibrous dysplasia.

Repair of Peripheral Nerve Lesions. T. I. Hoen.—p. 489.

Blood Donor Service of American Red Cross.—Thalhimer and Tisdall state that donations of 13,326,242 pints of blood were made by approximately 6,660,000 voluntary donors from Feb. 4, 1941 through August 1945. Donors averaged two donations. The American Red Cross Blood Donor Service was inaugurated at the request of the Army and Navy. The National Research Council assumed responsibility for endorsing all technical and scientific procedures and the Red Cross all other responsibilities. An ample supply of plasma was distributed to our forces all over the globe, to all ships, airports, hospitals and even to front lines and invasion beaches. Methods were developed for fractionating plasma, which proved useful for many purposes. When it was recognized that adequate treatment of hemorrhage and shock due to hemorrhage required immediate transfusion of whole blood, a project for the procurement of whole blood in the continental United States and its shipment to the various combat zones was jointly undertaken by the Army and Navy in cooperation with the Red Cross Blood Donor Service. On the basis of official reports, eye witness accounts and the related experiences of hundreds of army and navy physicians, it may be stated that the results of the use of whole blood shipped from the United States were most beneficial and that the reaction rate at least approximated the rates prevailing in the best civilian hospitals in this country. Some 380,000 pints of whole blood was procured, processed and shipped, with excellent results.

Bone Surgery of Hand.—Snedecor presents various types of bone surgery which have accomplished an improvement of function in severely deranged hands. Bone grafts have been used to form a first metacarpal, to make a bone block between the first and second metacarpals, and in many varied forms to make up loss of bone substance in metacarpals. A metatarsal head with its cartilaginous covering was successfully transplanted onto a metacarpal shaft to form a new metacarpophalangeal joint. Malunion of metacarpals often required correction by osteotomies to realine the metacarpal heads and restore the intrinsic muscle function. Rotation osteotomies were also useful to correct malunion of both metacarpals and the phalanges. Closing in of the hand by metacarpal shifts onto the bases of their vacant neighbors was discovered to be an advantageous procedure under proper indications. Simple arthroplasties of the metacarpophalangeal joints were practical and reasonably successful. Failures of union have been observed almost not at all either after osteotomies or after bone grafts.

Nephrosis Following Penicillin Therapy of Syphilis.—Scott and Clark report a case of secondary syphilis in a man aged 31 in which the classic nephrotic syndrome developed and which spontaneously and rapidly subsided without further antisyphilitic treatment following penicillin therapy. Treatment had been accompanied with a severe febrile Herxheimer reaction. This case demonstrates that subclinical involvement of the kidney may exist in early syphilis and that a focal Herxheimer reaction affecting a subclinically involved renal parenchyma may produce the nephrotic syndrome (syphilitic nephrosis).

Thiouracil Thyrotoxicosis.—Aranow and his associates review observations on thiouracil treatment of 77 cases of primary toxic goiter, 30 cases of recurrent toxic goiter and 47 cases in which thyroidectomy was done. They found that the incidence of "permanent" remissions obtained in primary thyrotoxicosis by the use of thiouracil is so small that they do not advocate it as the sole therapeutic agent. Prolonged treatment with thiouracil in primary thyrotoxicosis should probably be reserved for the categories of cases in which (1) operation has been refused, has been ineffective or is inadvisable, (2) malignant exophthalmos is feared, (3) the adolescent age group is involved or (4) roentgenotherapy has been administered without benefit and operation is not feasible. As a preparation for operation the use of iodine alone is advocated for the average case of toxic goiter because of the present incidence of toxic reactions with thiouracil and the length of time required for preparation with this drug. Thiouracil can be used to advantage as preparation for operation in the poor risk cases such as the thyrocardiac or those in which thyrotoxicosis is extreme and iodine is not tolerated or prolonged preoperative treatment is required. Thiouracil therapy is promising in a selected group of cases with recurrence of symptoms after operation. The permanent remissions in thiouracil treatment of recurrent toxic goiter are few but the drug does offer a means of control of hyperactivity over long periods.

Prevention of Wound Infection by Antibacterial Substances.—Howes says that a mixture of 200 units of streptomycin per cubic centimeter and 5 per cent of sulfamylon (4-amino-2-methyl benzene sulfonamide hydrochloride) was demonstrated as being capable of killing a three hour growth of bacteria on a blood agar plate. This combination of streptomycin and sulfamylon was demonstrated to be innocuous to tissues. It was suggested that the mixture of streptomycin and sulfamylon should be an ideal subcutaneous antiseptic. It was used in 30 clinical cases without untoward effects and without infection. The author made studies on animals. A defect 3 cm. square was cut in the skin of the back of the rabbit just lateral to the spinal column. The loose subcutaneous tissue and fascia were excised and the underlying muscle was vigorously crushed with a Kocher clamp. The wound was then contaminated with bacteria, either floor dirt or a twenty-four hour growth of a specific bacterium being used. The wound was then treated with the combination of streptomycin and sulfamylon. Infection was prevented when treatment was carried out immediately after infliction and contamination of the wound, but it failed to prevent infection in wounds treated three hours after infliction and contamination. The inclusion of the bacteria within leukocytes is offered as a possible explanation for the protection of the bacteria against the action of the antibacterials after three hours. Failing to penetrate to the bacteria within the leukocyte, the cell may subsequently die and liberate them unharmed to recontaminate the wound. Repeated injections and washing of the wound with an established localized infection did not hasten resolution of the suppuration. The author stresses that, if this combination of antibacterial substances is used clinically to prevent infection in wounds, the principles of good surgery should not be neglected. Use should be limited to contaminated wounds relatively free of traumatized tissue and foreign bodies. Other antibacterials can be substituted for the sulfamylon and streptomycin if they kill bacteria quickly in the presence of blood, have a wide range of activity, do not destroy or irritate tissue at the bactericidal concentration and are nontoxic.

Whole Blood Transfusions in Burns.—The 10 patients selected for the present analysis by McDonald and his associates suffered flame burns of from 30 to 80 per cent of their body surfaces and were treated under the direction of various members of the surgical staff of the Presbyterian Hospital, New York. The first 4 patients had overwhelming burns and appeared to have little or no hope of survival but are presented as a comparison of four types of shock therapy. Of the remaining 6 patients 2 died in the postshock phase and 4 survived. The authors conclude that replacement therapy in burn shock should be directed toward the restoration of all deficits in the circulating blood. Whole blood transfusions fulfil these requirements more nearly than any other single agent. Water and electrolytes can be administered to better advantage by mouth than by vein and will be absorbed in adequate amounts provided transfusions also are given. Sodium chloride solution in combination with lactate or bicarbonate is a more rational electrolyte mixture than sodium lactate solution alone in view of the tendency to alkalosis and hypochloremia which may result from vomiting and overalkalization in burn shock. The relative losses in plasma proteins and red cell mass may vary widely and are difficult to estimate during the period of hemoconcentration. In general, plasma losses will predominate in extensive second degree burns, while in third degree burns the red cell mass lost from the circulation may equal or even exceed the losses in plasma volume. During the healing phase of a severe burn whole blood should be administered in amounts adequate to overcorrect the anemia. If this is done the problem of maintaining nitrogen balance will be simplified. In the presence of anemia and hypoproteinemia uncontrolled electrocyte therapy by mouth or by vein is contraindicated since it will increase cellular edema and may lead to fatal pulmonary edema.

Dermatitis Due to Quinacrine Hydrochloride. F. T. Becker.—p. 338.

Allergic Dermatoses Complicating Penicillin Therapy.—According to Bauer, the reactions to penicillin are usually of an allergic nature and are then manifested clinically as some type of dermatitis. There are three clinical types of reaction to penicillin: (1) urticaria, (2) the erythematovesicular group of reactions and (3) contact dermatitis. The first two follow only the injection route, while contact dermatitis occurs only after external exposure. Although the exact allergen could not be identified in the 2 cases of contact dermatitis resulting from commercial penicillin sodium, studies indicated that neither crystalline penicillin sodium G nor the penicillin culture medium was responsible. An analysis of cases of the erythematovesicular type of reaction and the results of tests indicate that the mechanisms behind this erythematovesicular reaction and the dermatophytids are similar and may possibly be identical. The diagnostic value of intradermal tests in this group will be greatly increased if they are made in the dermatitic area rather than on the forearms. Cutaneous tests are of only limited value in the diagnosis of the three types of dermatitis discussed in this report. Identification of the exact allergens in these dermatoses must wait until more refined commercial preparations are developed and until the purified penicillin fractions become available for testing.

Changes in Coronary Arteries.—According to Ravin and Geever, Schlesinger's method for postmortem study of changes in the coronary arteries has opened a new field in the study of disease of these arteries. The authors examined a series of 166 hearts. In many cases the heart was normal, the cause of death being unrelated to it. The coronary arteries were occluded in 18 hearts. Seven specimens revealed more than one occluded vessel. Thirty-six hearts showed interarterial anastomoses. Anastomoses without occlusion were observed in 21 hearts. Occlusion with infarction occurred in 13 hearts. Occlusion without infarction was encountered in 5 hearts. Infarction without occlusion of the coronary arteries was found in 2 hearts. Some hearts showed uniformly hypoplastic arterial systems. The hypoplasia was considered a factor in the death of 1 patient with arteriosclerosis, thrombosis and subsequent myocardial fibrosis. In 11 patients over 80 years of age 9 hearts showed mild to moderate arteriosclerosis and scattered myocardial fibrosis. The other 2 showed advanced arteriosclerosis, anastomoses, occlusion and infarction. Anomalies of the coronary arteries involved mainly the left circumflex vessel. In 1 case the right coronary artery was absent. There is an important relation between the development of anastomoses and the prognosis and treatment of coronary arteriosclerosis and occlusion.

Meningococcic Septicemia.—Kinsman and his associates report 7 cases of proved fulminating meningococcic septicemia, with recovery in 2. In the beginning the illness was usually diagnosed as an ordinary infection of the respiratory tract. An eruption developed within three to twenty-four hours after the onset. Signs of shock appeared in twelve to twenty-four hours. Symptoms suggesting meningitis were usually present: Five of the 7 patients had pleocytosis; cultures of the spinal fluid of the same 5 patients yielded meningococci. Cultures of the blood of 5 patients were positive for meningococci. Albuminuria and azotemia were the rule. In 3 of the fatal cases adrenal hemorrhage was shown, while in the other 2 there were adrenal changes consisting of zonal degeneration and conspicuous congestion in the inner layers of the cortex, with "tubular changes" in the outer layer. In 1 case there were myocardial changes. It is believed that the cause of the circulatory collapse is the effect of the bacterial poisons on all the tissues of the body. The adrenal glands play only a part. A depletion of vitamin C may be a factor. The theory is advanced that the increased demand on the adrenal glands, as a result of the infection, depletes the cortical cells of their lipoid (hormone-containing) material; the cells degenerate more rapidly than normally, producing the "tubular" pattern in the outer layers and more conspicuous lesions in the inner layers, with eventual lysis of many of the cells before they have reached their usual site of death: this stage is considered reversible. Later, as a result of the loss of support of the sinusoids because of the premature death of the cortical cells, rupture and hemorrhage may occur—an irreversible stage. The patient may die before hemorrhage occurs. The primary aim of treatment is to overcome the infection. In addition to the supportive measures usually advocated, it is suggested that ascorbic acid might be of benefit.

Sequelae of Head Injury.—Kozol subjected 101 patients with acute head injuries to intensive study of multiple factors in the pretraumatic and the posttraumatic personality status. In a number of patients neurotic symptoms appeared for the first time after head injury. Psychologic changes were most noticeable shortly after discharge from the hospital and were at a maximum three to six weeks after discharge. In general they were receding at the end of three months. Approximately 50 per cent of the patients showed some persistence of symptoms at six months, and approximately 15 per cent had symptoms which persisted a year or longer. The duration of incapacity for work paralleled the persistence of psychologic symptoms. Patients with pretraumatic psychoneurotic personalities showed a greater proportion of posttraumatic psychiatric symptoms than did patients in other groups. There was no close correlation between the severity of the acute injury of the brain and the severity of the sequelae. There was high correlation between the existence of persistent complicating psychosocial factors, such as continuing compensation, pending litigation, occupational stresses and persistent associated bodily injuries, and the severity and persistence of psychiatric sequelae. The psychiatric sequelae were usually the resultant of various factors.

Healing Time in Peptic Ulcer.—Cummins and his associates found that accurate data are not available on the rate of healing of gastric ulcers, although the healing time of peptic ulcers is important in evaluating new methods of treatment and judging the efficacy of treatment in individual cases. In the 69 cases reviewed, fluoroscopic study and serial roentgenograms were taken on all original and subsequent examinations. All patients were subjected to the same therapeutic regimen. One teaspoon of a mixture of sodium bicarbonate and calcium carbonate in the proportion of 1 to 3 in water was given every two hours from 8 a. m. to 8 p. m. and at night if awakened by distress. The administration of alkalis was continued on this schedule for twenty-eight days; after that time they were given thirty minutes after meals, before retiring and on awakening at night. Half-and-half mixture of milk and cream 6 ounces every two hours from 7 a. m. to 9 p. m. was given for the first twenty-eight days of the regimen, following which the mixture was given between meals and in the evening. Food by mouth was begun on the fourth day by the gradual addition of farina, poached or boiled eggs, toast, puréed vegetables and ground, boiled or broiled beef. The healing time was judged by the time of disappearance of the crater radiologically. The average healing time for duodenal ulcers was thirty-seven days and for gastric ulcers was forty-two days. No correlation was found between the healing time and the size of the crater, age, recurrence or duration of symptoms.

Penicillin in Pyoderma.—Wrong has used penicillin extensively in the treatment of pyogenic skin infections for over two years. Bacteriologic studies are important in any investigation of the effect of penicillin in pyoderma. Staphylococcus pyogenes occurs in 90 per cent or more of all skin infections, and the percentage of its penicillin resistant strains is between 5 and 10. Penicillin has proved effective in the treatment of uncomplicated impetigo, ecthyma (the ointment being the method of choice) and erysipelas. Initial results may be good, but relapses are common, with sycosis of the beard, folliculitis, impetigo complicated by an underlying seborrheic dermatitis, otitis externa or sulfonamide dermatitis, and with furunculosis. Penicillin is of little or no value in common acne, rosacea and pyoderma caused by penicillin resistant organisms. The chief complications of penicillin therapy are dermatitis and urticaria. Dermatitis may develop in a few hours, a few days or even a few weeks after application of penicillin to the skin. The dermatitis subsides fairly rapidly with cold boric acid compresses. Benadryl appears to be of real value in controlling urticaria which follows administration of penicillin. The incidence of both complications seems to be increasing. The efficacy of this antibiotic is seriously affected by the complications.

Paraplegia Following War.—Botterell and his associates observed 103 posttraumatic paraplegic patients with stable spinal cord who were returned from overseas and were treated in Toronto at a center fully equipped and specially staffed to deal with all aspects of treatment and retraining during the period of February 1945 to June 1946. Forty-nine patients presented complete injuries of the spinal cord, while 54 had incomplete injuries, particularly in the lumbar and sacral regions. Death occurred in 7 instances and was considered to be due primarily to disturbances of nutrition, with genitourinary sepsis as a contributory factor. The treatment of the paralyzed bladder in these 103 patients, while overseas, consisted in suprapubic cystotomies in 77 and urethral drainage in 17; 9 had but transient retention requiring catheterization on a few occasions. At the center in Canada, tidal drainage remains the treatment of choice. Of the 77 cystotomies 61 have been closed, 24 by operation and 37 healed following institution of urethral drainage by a retention urethral catheter. In patients in whom infection with gram-negative urea splitting organisms was rife, administration of streptomycin was of substantial value and was continued until the suprapubic wound was healed and the urethral catheter removed. Anterior rhizotomy has been performed on 5 patients in whom the mass flexion reflex was disabling, and all have improved substantially. In 16 of 20 patients sacral, trochanteric and ischial pressure sores have been successfully closed with full thickness skin by rotation flaps. Bilateral pain tract section has proved of great value in the treatment of 4 patients with disabling pain who had lesions involving the cauda equina. Retraining commences while the patient is still in bed and gradually progresses. By grasping a bed frame exerciser the patient may be enabled to turn himself independently at two hour intervals by day and by night. Long leg braces of chrome molybdenum have been evolved and are put forward as being particularly suitable for paraplegic patients. Custom made boots of modified hockey cut type, light in weight and particularly flexible, are recommended as a means of preventing pressure sores of the feet.

*Relationship of Smoke to Pneumonia and Other Infections of Respiratory System. C. A. Mills.—p. 624.
Steam Locomotive and Atmospheric Pollution. C. A. Mills.—p. 634.

Relationship of Smoke to Pneumonia and Other Respiratory Infections.—Mills points out that certain industrial cities, as a result of their local topographical features, present sharp local differences in the degree of pollution. Cincinnati and Pittsburgh are two such cities. The sootfall in both cities is highest in the low lying areas of the river bottoms. The author cites figures which indicate the close relationship of high pneumonia death rates to heaviest sootfall. Atmospheric pollution with coal combustion products sharply increases the respiratory disease hazards of the inhabitants of an industrial city. Present day pneumonia and tuberculosis statistics in Pittsburgh and Cincinnati, showing death rates which rise sharply with increasing degrees of atmospheric pollution, provide emphatic support for the Ruhr basin findings of Ascher many years ago. Morton, in studying a large series of surgical records, found postoperative pneumonia to be six times more prevalent among patients who had been tobacco smokers up to the time of hospitalization than among nonsmokers. The author concludes that there exists a direct and highly significant relationship between air pollution and infectious diseases of the respiratory tract in man.

Differential Diagnosis of Peptic Ulcer.—Kirk presents a study that was made at the Station Hospital, Fort Sill, Oklahoma. In a sixteen month period 1,306 enlisted men were admitted to the gastrointestinal section. During this period 207 soldiers were proved to have peptic ulcer. There were 200 with duodenal ulcer and 7 with gastric ulcer, a ratio of 28:1. This report is concerned chiefly with the 200 cases of duodenal ulcer. Midepigastric pain occurring late at night and radiating into the mid back appears diagnostic of active duodenal ulcer. No correlation has been obtained between the gastric analysis and the severity of the ulcer or of the complaints. Free hydrochloric acid was absent in the fasting contents of the stomach in 26 cases and in the test meal contents in 12 cases. An increase in the total count and the percentage of polymorphonuclear cells is strong evidence of a penetrating ulcer. A duodenal ulcer has a 10 per cent chance of producing serious bleeding and a 5 per cent chance of perforating during its course. Alcohol and tobacco are not implicated as etiologic factors in this disease. The x-ray proof of ulcer was present in 100 per cent of this series. Comparing these 200 ulcer patients with 200 others in whom peptic ulcer had been suspected but could not be proved, it was found that the peptic ulcer patients as a whole showed no greater or lesser degree of psychiatric imbalance than patients with organic heart disease, tuberculosis or diabetes; that is, the emotional concept of the genesis of duodenal ulcer could not be proved.

Testosterone Propionate in Angina Pectoris.—Lesser treated angina pectoris in 92 men and 8 women with testosterone propionate. Twenty-five mg. of the hormone was administered twice a week for the first two weeks, followed by weekly 25 mg. injections, with an average of twelve injections in the whole series. No untoward effects were observed. Ninety-one of the patients improved for periods of from two to thirty-four months. No appreciable improvement was observed following control injections of plain sesame oil, although the same patients responded when placed on testosterone propionate therapy. Four patients were studied by exercise tolerance tests before and during the course of treatment. In each of these patients the amount of exercise which could be tolerated before the development of an anginal attack was vastly increased under testosterone therapy, and the severity of attacks, as measured by the duration of the pain, was correspondingly diminished. In each case subjective improvement was reported before objective changes could be demonstrated by the test employed.

Effect of Glutamic Acid on Mentally Retarded Subjects.—Albert and her associates administered glutamic acid to 8 persons with mental deficiency whose chronologic age ranged from 6 to 26 years and the mental age from 2 to 8 years. The I. Q. varied between 22 and 73. After the I. Q. level was established, the patients were given placebos or glutamic acid. An average of eighteen tablets a day of 0.5 Gm. each were given. A significant rise of mental age was found during the administration of the amino acid. During the successive placebo period the patients' I. Q. dropped back to the level maintained before glutamic acid was given. The authors do not wish to imply that cases of secondary mental deficiency and other forms of feeblemindedness may be cured with glutamic acid; but there is some indication that a limited influence can be demonstrated on some of these patients. Mental defects have been considered unalterable, and treatment has been concentrated on the social and educational aspects. The authors felt that attempts should be made to test the possibility of improving brain function by biochemical means. The results obtained with glutamic acid are considered to be a starting point for further investigations.

Dietary Oxalate and Rat's Teeth.—Gortner and his associates demonstrated that ingestion of solutions of various food acids (phosphoric, citric, lactic, sulfuric) caused considerable destruction of rat molars. They found in feeding experiments on young white rats that small amounts of soluble oxalate in the food or drink produced a hard deposit on the teeth of the animals which grossly resembled human dental calculus. The extent of this encrustation, which is presumably calcium oxalate, varied with the concentration of oxalate consumed and with the length of the experiment. Because of this phenomenon, oxalic acid solutions did not etch the enamel of the teeth of rats, in contrast to the action of other common food acids (citric, lactic, phosphoric, sulfuric). When oxalic acid or its sodium salt was present in the rat's food or drink the decalcification of teeth which accompanies ingestion of phosphoric (0.055 per cent) and citric (0.20 per cent) acid solutions diminished or disappeared. Protection against the etching action of orange juice was afforded by a concentration of 0.1 per cent oxalate in the juice.

Free Chlorination of Public Water Supplies.—DeKleine and Faust discuss the advantages of "free chlorination," more generally known as breakpoint chlorination, which is the treatment of public water supplies that has been introduced in a number of Michigan communities. They cite the case of a small city in western Michigan where the source of the water was an inland lake. Algae and weed growth were luxuriant. This unfiltered water was treated with the usual amount of chlorine, about 1.5 parts per million, and also about 0.1 part per million of ammonia. This provided a chloramine (combined chlorine) residual of between 0.3 and 0.5 part per million at the pumping station. The resulting tastes were so objectionable that the residents had to depend largely on bottled water for drinking purposes. It was recommended that the ammonia application be discontinued and that the chlorine treatment be increased in an amount sufficient to produce a residual of free chlorine.

Tyrothricin in Surgical Infections.—Kozoll and his associates say that tyrothricin which contains both gramicidin and tyrocidin could combine the bacterial potency of the fomer with the stability and solubility of the latter. They studied the clinical effectiveness of tyrothricin by using it as a wet dressing in treating 77 patients with surgical infections, the majority of whom had failed to respond to other methods. Fifty of the 77 patients had excellent clinical results, 8 had fair clinical results and 19 had poor results. Tyrothricin, when used on one of the bilateral lesions in 6 cases, produced in 5 either a more rapid rate of healing, less pain and exudate, or a greater bactericidal effect than control measures in the contralateral lesion. It was most effective in hemolytic streptococcus lesions, next in those with Staphylococcus aureus and albus. It was ineffective when the preponderant organisms were gram negative. Tyrothricin appeared to encourage the growth of pseudomonas, pyocyaneus and diphtheroid organisms, but it did not produce anemia or hemolysis. Tyrothricin treatment was associated with mild skin reaction in 3 patients; these reactions disappeared when treatment was discontinued in 2 instances, and in spite of continuation of therapy in the third. Tyrothricin is recommended as a nontoxic, noninjurious antibiotic agent for local use in the treatment of surgical infections, if the wound is open, if there is adequate surgical drainage, if there is adequate blood supply and if the predominant organisms are streptococci or staphylococci or both.

Identification of Clostridium Welchi and Determination of Sensitivity to Penicillin.—Heller and his associates show that a rapid bacteriologic method for identifying gas gangrene organisms may be an aid in the management of contaminated wounds. At their laboratory the production of acrolein from glycerol has been used as the basis for a rapid test for Clostridium welchi. This procedure depends on (1) the aerobic growth of anaerobes in a specially prepared medium, (2) the development of acidity which determines the testing time for acrolein and (3) the testing for acrolein in the culture medium with a standardized Schiff's reagent. The inhibition of acrolein by the penicillin in the medium was taken as a measure of penicillin sensitivity.

Cancellous Bone Grafts for Infected Bone Defects.—Coleman and his associates, over the past fourteen months, have cleaned out 52 infected bone defects, filled them with cancellous chip grafts and closed them without drainage. The patient is treated with 20,000 units of penicillin intramuscularly every three hours, two days before operation. This is continued postoperatively until his temperature has remained normal from two to five days. At operation all scar tissue, granulation tissue and sequestrums are removed. The cavity is excised with an osteotome or curetted down to healthy bleeding bone. The wound is washed out and penicillin sulfathiazole powder is sprinkled liberally. The grafts are taken from the iliac crest. A trap door of cortical bone with attached periosteum is raised from the crest of the ilium. A wedge of cancellous bone can then be cut and further bone obtained with a curet. The wedge of cancellous bone is shaved with a sharp osteotome into thin chip grafts. The cavity is filled with chips and penicillin powder held together with coagulated autogenous plasma. One to 2 cc. of 0.2 per cent sterile agar is added as a coagulant. The tibia was involved in 29 cases, the femur in 12, the os calcis in 3, the humerus in 6, the carpus in 2. In all 52 cases infection was present at the time of operation, but no virulent infections have resulted and there has been no flare-up of infection after healing for periods up to fourteen months. The one stage method for obliterating infected bone defects saves months of hospital treatment and restores function before changes from disuse become irremediable.

Para-Aminobenzoic Acid in Endemic Typhus.—According to Levy and Arnold murine typhus is endemic in Texas and has considerably increased. They report 6 cases of murine typhus observed in the Medical Service of the Southern Pacific Hospital in Houston, Texas. The diagnosis was made on clinical symptoms and findings and by the determination of the Weil-Felix reaction. Since para-aminobenzoic acid inhibits the growth of rickettsiae and had proved effective in an epidemic of louse borne typhus fever, the authors used it in the aforementioned 6 cases, administering 2 Gm. every two hours. The drop in temperature and relief of symptoms were almost dramatic in their effect. No side effects were noted.

Pyridoxine in Radiation Sickness.—According to Shorvon pyridoxine is a member of the vitamin B group occurring principally in liver and yeast. It can be obtained in tablets for oral use and in ampules for intravenous medication. The author employs the tablets, giving five 10 mg. tablets daily. Occasionally he gives intravenous injections of two ampules (each containing 50 mg.) a week. In addition to its value in the treatment of radiation sickness, it increases the leukocyte count. This is of importance because of the tendency for x-rays to depress the white cell count. The author used pyridoxine in the treatment of 24 cases of radiation sickness. Good results were obtained in 22 of these.

Staphylococcic Spinal Osteomyelitis with Acute Extradural Abscess. G. Blackburn and R. P. Jepson.—p. 297.

Tobacco and Ulcer Dyspepsia.—Jamieson and his associates report a follow-up survey of 473 patients who had suffered acute perforation of a peptic ulcer from one to five years previously. They were recalled for examination and were closely questioned about their smoking habits. Heavy cigaret smoking was associated with severe symptoms, but pipe smoking with mild symptoms. It is suggested that the relationship between smoking and severity of symptoms is indirect and depends on age: symptoms tend to be severe in the young and mild in the old. Cigaret smokers are in the main young, while pipe smokers are in the main old. There was no evidence that increase or decrease in tobacco consumption influenced the severity of symptoms.

Curarine with Balanced Anesthesia.—Gray and Halton state that this anesthesia is suitable for all endoscopic investigations, but particularly for bronchoscopy and esophagoscopy by virtue of the complete relaxation of the vocal cords and the pharyngeal sphincter. A single injection of 15 mg. of curarine (d-tubocurarine) is followed by a suitable dose of a barbiturate, both given intravenously. Administration for longer procedures is essentially a balanced anesthesia. After induction the patient is maintained in a light plane by means of an intravenous barbiturate. The author stresses that curare should not be considered merely as an "aid" to anesthesia: it is an integral part of the anesthetic procedure. This is by virtue of four important properties: (*a*) It is quickly eliminated, leaving no toxic aftereffects; (*b*) it produces relaxation as and when desired; (*c*) it abolishes laryngeal and bronchial spasm, making intubation of the trachea necessary only in selected types of cases; (*d*) because of the undoubted synergistic action with the anesthetic agents, the dose necessary to keep a patient asleep can be considerably reduced. If these four properties are borne in mind, and if a correctly balanced anesthesia is maintained, patients after long abdominal and thoracic operations are awake, in good vasomotor equilibrium, free from nausea and able to exert their respiratory functions to the full. There is in consequence a smooth postoperative convalescence.

Surgery of Hand Infections.—Kinsella uses the term "pad infections" for the subcutaneous infections which tend to become localized in the palmar fatty pads. Pad infection I, the so-called felon, involves the distal phalangeal pad. Pad infections II and III involve the middle and proximal phalangeal pads respectively. Suppurative tenosynovitis may occur as a later complication. Pad infection IV involves the pads in the distal part of the palm and may spread to the web. It is usually due to infection occurring beneath a callosity, whereas infection in the first three pads is usually due to a puncture wound. Pad infections II and III may be distinguished from acute suppurative tenosynovitis; in acute suppurative tenosynovitis the swelling of the finger is uniform and the finger is sausage shaped; in pad infections the swelling is most pronounced over the affected pad, and the finger is spindle shaped. Incisions required to evacuate pus in pad spaces II, III or IV may be C shaped or cross shaped. The author uses for postoperative treatment the method which imitates the Winnett Orr technic. Dressings are changed infrequently, usually once a week. He regards the sulfonamides and penicillin as important additions. Erysipeloid infections occur in those handling fish and pigs. In these cases an ill defined area of inflammation spreads diffusely and irregularly from a slight injury. Operation is not indicated, for pus does not form. This infection is self limited.

Treatment of Ulcerative Colitis with Intestinal Mucosa.—Gill states that the cause of ulcerative colitis in some cases may lie in a deficiency caused by the lack of some factor produced by the small intestine. Treatment of some cases of ulcerative colitis with intestinal mucosa has given promising results. There is a latent interval of about three weeks before any appreciable improvement is noted. Mucosa taken from the different segments of the small intestine seems to be effective, although possibly jejunal mucosa produces a more lasting effect.

*Twenty Years of Treatment of Diabetes Insipidus by Nasal Administration of Powdered Posterior Lobe of Pituitary. A. and Lucie Choay. —p. 500.

Treatment of Diabetes Insipidus by Nasal Administration of Powdered Posterior Lobe of Pituitary.—The Choays have used this method for twenty years to control thirst and polyuria in more than 100 cases of diabetes insipidus. The powder is obtained by pulverizing and sifting posterior lobes of beef pituitary glands previously dried in a vacuum and in the presence of sulfuric acid or dehydrated by acetone. One ox supplies about 0.08 Gm. of powder, i. e. about one daily dose. The powder is taken into the nose in the same manner as snuff. The patient should blow his nose prior to the administration of the powder but should not blow his nose or sneeze for several minutes afterward. The best results were obtained with three to five doses of 0.01 Gm. in the course of one day and with 1 dose of 0.02 Gm. at night before going to bed. In cases of severe polyuria, mixed treatment by nasal administration of powder during the day and by an injection of 10 mg. at night is suggested. In the average case the effect of the powder when administered correctly to a healthy nasal mucosa lasted for three to six hours during the day and for six to ten hours during the night. The contraindications to the method are hypertrophic rhinitis, chronic rhinorrhea and spasmodic rhinitis. Even a simple coryza may cause failure and favor local infection. Preliminary anterior rhinoscopy, therefore, is as important as a preliminary injection of the extract. Failure of nasal administration of the powder is to be expected in the case of failure of the preliminary injection.

*Endocrine Treatment of Carcinoma of Prostate. G. Reimann-Hunziker. —p. 449.
The Notion of Alimentary Equilibrium in Daily Practice. L. M. Sandoz. —p. 452.

Endocrine Treatment of Carcinoma of Prostate.—According to Reimann-Hunziker only radical operation of a carcinoma of the prostate brings prospects of a complete cure. This treatment is rarely possible because the patients come under medical care too late. All other treatments are merely palliative. Castration and estrogenic therapy may prolong life and in many cases pains and dysuria may temporarily disappear. Improvement is usually most rapid if castration is followed by a transurethral electroresection with subsequent protracted medication with diethylstilbestrol. With this combined treatment the longest average survival is obtained. Occasionally improvement of the general condition is so good that the patient may be able to work again for a while. The primary tumor as well as the metastases may regress. However, neither castration nor estrogenic therapy will prevent metastatization. Improvement is always only temporary and persists for only about six months or somewhat longer. The hope that the tumor might regress sufficiently so that it might become operable has not been realized. The determination of the serum phosphatase will, if it is positive, give information about the prognosis and the efficacy of a treatment. A high phosphatase value suggests bone metastases.

*Erythroblastosis of Newborn Infant with Rh Positive Mother Sensitized by Rh Factor. M. A. Etcheverry.—p. 83.

Erythroblastosis of Newborn Infant.—In 80 mothers of infants with erythroblastosis fetalis Etcheverry found the blood Rh negative in 69 (87 per cent) and Rh positive in 11 (13 per cent) of the cases. In 1 instance the blood of both parents and of the infant with the icteric type of erythroblastosis was of the O group and Rh positive. The blood subtypes were different, namely, Rh′ for the mother and RhO′ for the father and the infant. Anti-Rh antibodies of Anti-RhO specificity were encountered in the mother's blood. Successful therapy consisted in blood transfusion every three days up to a total of five transfusions, for which blood of the group, type and subtype of those of the mother was used. Injections of vitamin K and of liver extract were also administered to the infant.

Penicillin Through Duodenal Tube in Gastric Surgery.—Dwek and Mandl point out that the acidity of the gastric juice is reduced after operations on the stomach because of the removal of the hydrochloric acid producing glands in subtotal gastrectomy and the regurgitation of the alkaline bile into the stomach after a well functioning gastroenterostomy. They administered penicillin through the duodenal tube to 7 patients, to 4 after subtotal gastrectomy and to 3 after gastroenterostomy. The dosage varied, some patients being given doses of 12,500 and 6,500 units, others several doses of 25,000 or 50,000 units and still others a single dose of 100,000 units. The level of penicillin in the blood serum was within the therapeutic range in 5 of the patients. The duodenal tube method avoids the unpleasant effects of the numerous injections necessary with the parenteral route of administration.

Scarlet Fever and Its Complications.—In 1,061 cases of scarlet fever from 1940 to 1944 in patients aged from 6 months to 65 years the mortality was 0.2 per cent. Most cases occurred during the winter months. The frequency of complications seemed unrelated to the age. Lymphadenitis occurred in 28 per cent, otitis media in 10 per cent, arthralgias in 7 per cent and nephritis in 3 per cent of the cases. Søndergaard states that early treatment with scarlet fever convalescent serum did not prevent complications; sulfanilamide early in the course perhaps reduces the number of complications. Erysipelas and otitis media should be treated with sulfanilamide or sulfathiazole; in lymphadenitis their effect is doubtful. Application of these agents in treatment of the other complications appears useless. The high sedimentation reactions are caused mainly by the arthralgias, the long periods of hospitalization mostly by nephritis and otitis media.

Book Notices

Diabetes: A Concise Presentation. By Henry J. John, M.A., M.D., F.A.C.P. Cloth. Price, $3.25. Pp. 300, with 74 illustrations. St. Louis: C. V. Mosby Company, 1946.

This book represents the accumulated interest of its author, whose experience has been large and intensive. It contains much that is sensible and good, and even when the reader will feel that he cannot subscribe to the author's dicta he will still be indebted to him for having challenged his point of view. The volume is not an all inclusive discussion of the subject of diabetes. It is intensive in some phases and passes lightly over other phases of the subject. That to a certain extent is inevitable in any monograph. It would be more apt to appeal to the seasoned practitioner than to a student of medicine, and yet the practitioner who is not experienced in the handling of diabetic patients also needs systematized guidance and approach. When all is said and done, in dealing with the description of a disease it is best accomplished by considering its etiology, pathology, symptoms, diagnosis, complications and treatment in classic nosographic style. No one has yet found a better way. When this systematization is ignored, whether each chapter or section is designated as such is not as important as is a logical sequence in the presentation. Otherwise the usefulness of a book may be definitely impaired because valuable passages and observations may be misplaced and remain unnoticed. John has devoted a medical lifetime to diabetes, and his book describes many of the ins and outs of the subject. His book is a greater contribution to the subject of diabetes than that of the publisher to the art of bookmaking. This shortcoming can be charged only in part, to the war and its aftermath.

Nursing and Nursing Education. By Agnes Gelinas, R.N., A.M., Professor of Nursing and Chairman of the Skidmore College Department of Nursing—New York Post-Graduate Medical School and Hospital, New York. Studies of the New York Academy of Medicine, Committee on Medicine and the Changing Order. Cloth. Price, $1. Pp. 72. New York: Commonwealth Fund; London: Oxford University Press, 1946.

Consistent with the type of book sponsored and published by the Commonwealth Fund, this edition has the meat of the problem clearly stated. It is a surprisingly small volume for so much information. A brief summary of past developments precedes the outlining of contemporary problems with the advice "Nor is the maintenance of standards, once they have been attained, sufficient: to have reached a goal is commendable, but the ground gained must be held and new ground won." The necessity of changes in present day educational methods is justified by the choice of a few but exceptional statistics which drive the points home. Future developments indicate that a larger number of qualified nurses will be needed during the next ten years than has ever been experienced before in our country. The demand is really being exerted now—before an adequate number of specially trained nurses can be supplied for the specialties that are developing in nursing as they have developed in the practice of medicine. Estimates indicate that 355,000 graduate nurses will be available in 1948, but the postwar requirements for the country call for 485,600 full time registered professional nurses. The need for larger classes in the face of elevation of educational standards is obvious.

Recreation and the Total Personality. By S. R. Slavson. Cloth. Price, $3. Pp. 205. Association Press, 347 Madison Ave., New York 17, 1946.

There are few books to date which put recreation into perspective as a derivative of man's basic nature as does this publication. This postwar volume is most timely, because in these days of reduced work hours, automatic labor and time saving devices, leisure time is on the increase. How can recreation make its maximum contribution to the total well-being and wholesome living of individuals and communities? Practitioners, recreationists, educators, sociologists, community organization leaders, social and group workers, hospital and institution staffs, parents-teachers, work foremen and the general community will do well to read this book, as from it emerges a concept of recreation embracing the insights of mental hygiene, education, psychology, sociology, social work and group work. The ten chapters which comprise the book are on the nature and scope of recreation, unconscious motivations, fitting recreation to the individual, recreation and the democratic culture, the problem of competition, a demonstration of the new recreation, constants, variables and differentials, leadership and recreation, supervision: a creative relation, and community resources. The author suggests technics that lean less on a stock of artifices, games and facilities and more on an individualization that will balance the deprivations from which we suffer, such as physical underfunctioning, frustration of unconscious drives, devaluated self esteem, lack of self assertion and inadequate creative expression. Recreation is a part of the total educational experience of man in modern society. Its value can be realized only when some traditional views of recreation are modified or eliminated.

Eléments de psycho-physiologie. Par Henri Roger, professeur honoraire de physiologie à la Faculté de médecine de Paris. Paper. Price, 350 francs. Pp. 428, with 20 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e, 1946.

This book, written by a French physiologist, purports to put psychology on a sound and scientific basis. It is too voluminous for an introduction and much too superficial for a textbook, besides lacking bibliography or index. Heavily weighted in favor of French literature, it starts out with a short reflexology, not taking into account modern research on reflexes of posture, vestibular reflexes, and so on. This is followed by a purely descriptive treatment of instincts, of which the author seems to recognize about six: the instincts of alimentation, defense, reproduction, motherliness, gregariousness and migration. He also mentions an instinct of play. In the following part the intellectual acts are based predominantly on cerebral function. The emotions are treated descriptively. The author differentiates between primary emotions (fear, anger and love) and secondary emotions, under which heading one finds a motley assembly such as feelings of justice, of religion, of beauty. Of gestalt psychology, analytic psychology, the author has only the vaguest notion. The few times he mentions Freud he misquotes him (for instance, accusing him of reducing all instincts to the reproductive one or ascribing the causes of all dreams to the unconscious memory of erotic stimulations). In the final part, on psychophysiologic functions, one finds a treatise on determinism and freedom, chapters on heredity, periodicity (including a short review on electroencephalography), sleep and dreams, and 20 pages on consciousness and the unconscious acts, omitting, of course, the large body of research on the dynamics of the unconscious.

Endoscopia normal de la uretra membranosa y del cuello del bulbo. Por Hector Diaz Castro, profesor agregado de urología de la Facultad de medicina de Montevideo. Este trabajo fué presentado como tesis, al concurso para profesor agregado de urología de la Facultad de medicina. Paper. Pp. 151, with 55 illustrations. Imprenta "Rosgal," de Hilario Rosillo, Montevideo, Uruguay, 1944.

In contradistinction to the extensive studies reported on the anatomy of the prostatic and anterior urethra, the membranous urethra and bulbar urethra seem to have been neglected. Nor do existing descriptions correspond accurately with the actual morphologic and anatomic conditions observed endoscopically. The author presents his own conception based on several years' study of the region, which is influenced throughout most of its course by the interplay of muscles and the intricate complex composed of the musculoaponeurotic combination known as the urogenital diaphragm. The dynamic character of the area renders cadaver studies misleading, the postural variations due to muscular activity producing transitory morphologic changes. In the cadaver the urethral muscle is fixed. Endoscopy of the urethra has hitherto been largely limited to the prostatic and anterior urethra and verumontanum, the sites of predilection for most tumors and inflammatory changes. After reviewing the classic conceptions based on the anatomic studies on the cadaver, the author proceeds to describe the technic for endoscopy of this particular region and presents certain anatomic and physiologic deductions based thereon. Following a review of endoscopic findings, these are compared with the histologic anatomic findings in various stages of embryologic life and in the adult.

The endoscopic images are all interpreted in relation to roentgenograms of the normal states of dilatation and contraction: The physiology of the membranous urethra and neck of the bulbar urethra is explained, including a discussion of sympathetic and voluntary innervation, the special physiology of the membranous urethra, of the bulbar genital function in ejaculation. Also the physiopathology of the membranous urethra in neurogenic hypertonic and hypotonic vesical disturbances is demonstrated, as well as their endoscopic aspects. It is emphasized that the canalicular and muscular systems form an inseparable complex of primary and accessory muscles controlled by the sympathetic and voluntary nervous system. The interbulbomembranous sheath serves as a point of fixation for the urethra and as a support for its motor muscle. He concludes that almost the entire dynamism of the membranous urethra is located in the median portion of the inferior wall, which he describes as the poculiform portion. The other portions play a much less significant physiologic role. In the final chapter he discusses the extremely rare congenital malformations of the membranous and bulbar urethra, with a description of 2 cases.

Disorders of the Blood: Diagnosis, Pathology, Treatment and Technique. By Sir Lionel E. H. Whitby, C.V.O., M.C., M.D., Regius Professor of Physic in the University of Cambridge, Cambridge, and C. J. C. Britton, M.D., D.P.H., Assistant Pathologist, The Bland-Sutton Institute of Pathology, The Middlesex Hospital, London. Fifth edition. Fabrikoid. Price, $10. Pp 665, with 86 illustrations. Philadelphia: Blakiston Company, 1946.

In preparing the fifth edition of their widely known work the authors have made extensive revisions in the chapters dealing with the origin and development of the blood cells, the hemolytic anemias, the anemias of infancy and childhood, agglutination of the red blood cells and blood transfusion and technic. The text has been lengthened, and there are some new colored illustrations of the bone marrow. Although greatly disturbed by the war, the authors have nevertheless done their utmost to keep the material up to date. This has been particularly difficult in view of the rapidly changing views regarding the Rh factors. Much of the best research on the blood is now being carried on in laboratories in the United States, and much which was not easily available during the war is now becoming for the first time common knowledge. The authors have done a great deal to acquaint themselves with recent advances in the United States, but a new edition will probably be necessary within a short time if all essential new information is to be added.

Principles of Radiography. By C. B. Minnich, B.Sc., R.T. Fabrikoid. Pp. 130, with 43 illustrations. Kansas City, Missouri: The Author, 1946.

Because it contains essential elementary principles of the science of radiography in clear but concise form, this monograph makes an excellent handbook for the novice learning to operate x-ray equipment. Especially good is the review of the elementary physics of electricity and the description of the electrical setup of the x-ray machine. In addition, chapters on the subjects of radiation, the darkroom, the calibration, technical variations and x-ray protection are dealt with. This book was meant to be only a brief primer in basic study of x-rays and therefore does not concern itself with such topics as positioning, fluoroscopy or interpretation of x-ray films. Because it may be easily and quickly read and understood, the book is recommended to physicians who desire a summary knowledge of the physics of x-rays. It is highly recommended for use by student x-ray technicians.

Health from the Ground Up. By Karl B. Mickey. Paper. Pp. 125. Chicago: *International Harvester Company*, 1946.

Here is a provocative essay on the relationship between health and the soil in which food crops are grown. The author, who is in the public relations department of the International Harvester Company, believes that "exhaustion of the soil has been an important factor in the decline of civilizations" and that every effort must be made to secure more information on the relationship between the soil and human health. The material is well written, and there are many quotable statements throughout the book. An excellent bibliography of more formal treatments of the subject is appended.

The Results of Radium and X-Ray Therapy in Malignant Disease: Being the Second Statistical Report from The Holt Radium Institute, Manchester, Now Part of the Christie Hospital and Holt Radium Institute, Years 1934-1938 Inclusive, Assessed at 5 Years, and 1932 and 1933 Assessed at 10 Years. Compiled 1945 by Ralston Paterson, Margaret Tod and Marion Russel. Paper. Price, 7s. 6d. Pp. 147, with 3 illustrations. Edinburgh: E. & S. Livingstone, Ltd., 1946.

This is the second statistical report from the Holt Radium Institute, Manchester. The first part is a general survey of the treatment of cancer as a whole and is intended to interest the layman, the hospital administrator and the general practitioner. The second part is an evaluation of different methods of treatment. The technics are described and reference is made to publications in which may be found a full account of the physical principles together with detailed instructions for specialized methods. The third part refers briefly to the first report and gives a table showing the ten year results of treatment. The authors state that radium and x-rays are equally important, that each has advantages and that the two agents are often complementary. The tables are so arranged as to give the results of radiotherapy in various stages of the disease, thus permitting statistical comparison of different methods. The report represents a careful and complete study of the results of radiotherapy in a large group of cancers extending over a period of many years. It should be of interest to the physician as an indication of the role of radiotherapy in cancer as well as to the specialist, who is interested in the details of treatment. The research covered by the report constitutes a fundamental contribution to clinical cancer research.

Encyclopedia of Endocrinology. By Hans Selye, M.D., Ph.D., D.Sc., Professor and Diector of The Institute of Experimental Medicine and Surgery, University of Montreal. Section IV: Ovary. Volume VII (in two parts): Ovarian Tumors. Bibliography. Fabrikoid. Price, $21.75. Pp. 349, with 427 illustrations. Montreal: Richardson, Bond and Wright, 1946.

Dr. Hans Selye, convinced of the importance of the complete knowledge of the available literature for the study of any subject, began a long time ago to collect a library dealing particularly with endocrinology. His library now contains approximately 250,000 entries. The Encyclopedia is a step toward making that material generally available. The first publication was the "Classified Index of the Steroid Hormones and related Compounds," published in 1943. Now come two volumes on "Ovarian Tumors," which constitute part of section IV, which will be devoted to the ovary. The entire encyclopedia is to consist of ten sections covering all the glands of internal secretion. The encyclopedia is loose leaf, so that it may be kept up to date by the addition of new material. Every publication referred to is suitably indexed by number, so that reference may be had to the original source. The first two volumes are magnificently illustrated and written with an economy of style and diction highly commendable in a work of this type. There is a complete subject index and a bibliography of the periodicals concerned. The second volume is devoted wholly to the bibliography of ovarian tumors.

The Art of Medicine in Relation to the Pregress of Thought: A Lecture in the History of Science Course in the University of Cambridge, February 10, 1945. By A. E. Clark-Kennedy, M.D., F.R.C.P., Physician to the London Hospital and Dean of the Medical School, London. Paper. Price, 75 cents. Pp. 48. New York: Macmillan Company; London: Cambridge University Press, 1945.

The publishers have made available in pamphlet form this lecture in the History of Science course. After reviewing briefly the progress of medical science, Dr. Clark-Kennedy concludes his address with a consideration of medicine and modern life. He fears the development of a medical science from which the humanities will have been lost. Thus he says "We live in an age in which scientific knowledge has outrun philosophy, narrow specialization is the order of the day, religion has ceased to be a unifying force in education, belief in the Christian revelation seems to have declined, and excessive anxiety over the health of the body has replaced preoccupation with the welfare of the soul. Humanity seems to be traveling through the night without any white line to keep us in the center of the road."

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

NEWER FUNGICIDES

To the Editor:—What new remedial measures are indicated in the treatment of epidermophytosis and other fungous infections? I have been informed that recent work by military organizations has resulted in the selection of remedies which are more or less specific in these cases.

Edwin R. Watson, M.D., Macon, Ga.

Answer.—A number of promising therapeutic agents for the treatment of fungous infections have been adequately tried during the war years. The most important new development has been the use of mixtures of fatty acids and their salts such as *sodium or calcium propionate*-propionic acid mixtures. These compounds were found to be effective against human pathogenic fungi. They have also been used with good therapeutic results *in otomycosis and oidiomycosis, thrush and blacktongue.* The propionates are used in 10 to 30 per cent concentration in liquids, powders and ointments. Favorable results have also been reported following the use of undecylenate-undecylenic acid ointment. However, a number of observers have preferred the propionate-propionic acid preparations to the undecylenates. Evidence is accumulating which seems to indicate that mixtures of propionates and caprylates are the most effective of the fatty acids so far tried.

PROLONGED USE OF NASAL VASOCONSTRICTORS

To the Editor:—What are the potential effects on the nasal mucosa of a vasoconstrictor such as neosynephrin administered daily for many months?

M.D., Illinois.

Answer.—Several reports of undesirable effects from prolonged use of vasoconstrictor substances in the nose have appeared in literature in the past few years.

Experimentally the action of the cilia has not been depressed by such vasoconstrictor substances as ephedrine, neosynephrin, tuamine and some related substances in appropriate concentrations, and injurious effect to the mucosa has not been observed. While these drugs have had a therapeutic value in certain acute or subacute conditions, the prolonged use of at least two of the group (ephedrine and privine) has on numerous occasions been observed to cause an undesirable reaction in the nasal mucosa which is relieved only for a brief period by the vasoconstrictor effect. The mucosa becomes congested and has a diffuse dull red somewhat dry and irritated appearance and the airway is obstructed. Elimination of all intranasal medication in such cases has been followed by relief of symptoms within three to four days. A permanent pathologic change in the mucosa as a result of the use of vasoconstrictors has not been reported.

The cause of the congestion appears to be that the vasoconstrictor action is associated with irritation and is followed by vasodilatation and increased congestion.

Such a reaction frequently has been observed after the use of epinephrine, which has a strong vasoconstrictor effect. Repeated usage of vasoconstrictors produces a continuous state of irritation and mucosal congestion which can be termed a chronic rhinitis due to medicaments.

SCOPOLAMINE IN OBSTETRIC ANESTHESIA

To the Editor.—Please discuss the use of scopolamine in obstetric anesthesia. Scopolamine 1/150 to 1/100 grain (0.4 to 0.6 mg.) as preanesthetic medication should reduce mucous secretions in the respiratory tract. If the time is short, it has been suggested that the drug be given intravenously in the same dosage. Will this procedure have untoward effects on the mother and/or the baby?

M.D., Pennsylvania.

Answer.—Scopolamine in the dosage mentioned would certainly minimize mucous secretions. However, a smaller dose has been found adequate for the purpose even when given by hypodermic injection. There is no objection to giving scopolamine intravenously well diluted. One three-hundredth grain (0.2 mg.) or at most ½00 grain (0.3 mg.) has proved adequate. Neither this nor larger doses have any serious untoward effects on either mother or child. The accompanying psychic sedation is desirable. Larger doses do sometimes cause excessive dryness of the mucous membranes which is unpleasant to the mother.

SUN GLASSES

To the Editor:—Please discuss the harmful or beneficial effects on the eyes of the average sun glasses sold in drug stores and dime stores throughout the country.

Paul N. Taylor, M.D., Washington, D. C.

Answer.—Many poorly fitting and cheap glasses cause ocular distress and headaches; a person who has such distress when he wears glasses naturally takes them off, just as a man takes off a pair of shoes that do not fit him comfortably.

The light from which our eyes are protected by "sun glasses" may be considered as follows: (*a*) Sunlight: Very bright sunlight is distressing in varying degrees to all eyes. This is the reason why the eyelids are kept closed, or nearly closed, when one is facing such a light. (*b*) Ultraviolet: Ultraviolet light of the wavelength of approximately 300 millimicrons, such as is present in a rarefied atmosphere on high mountains or in dense snow fields, or such as comes from arc lights or welding machinery, causes irritation and temporary inflammation of the superficial cornea and conjunctiva, coming on eight to twenty-four hours after exposure and lasting a day or more. Welders, for instance, are protected by special goggles. (*c*) Infra-Red: Eclipse blindness is a burn of the macular area, a result of the infra-red rays, and comes on immediately and is permanent. Smoked glasses are used to prevent this in those who wish to look at an eclipse. (*d*) Glare: Almost all of us are made uncomfortable by "glare"; but pathologic lesions produced by "glare" have not yet been found.

The average sun glasses, obtained in drug and ten cent stores, if sufficiently dark, are as a rule comforting to the eyes of the average wearer on an average bright day, on the water or on the beach where they are usually used. They reduce the total amount of light entering the eyes. The idea that certain makes of glass do not transmit the "harmful" ultraviolet light is mostly sales talk, as the ordinary white glass allows but little ultraviolet light to pass through. In fact, in order to obtain passage for ultraviolet through a window pane it has to be specially made for that purpose. A certain amount of ultraviolet light is beneficial to the eyes; it is for this reason that vacations are taken at the seashore and in the mountains, and in the winter patients are sent to sunny climes.

VITAMIN K

To the Editor:—Is there any danger in the prolonged daily administration of 2 mg. of menadione in a case of intestinal hemorrhage of unknown origin? There is no evidence of prothrombin deficiency. A multiple vitamin capsule includes 10,000 U. S. P. units of vitamin A and 1,000 U. S. P. units of vitamin D. What deleterious effect might be produced by the prolonged administration of one capsule daily in the case referred to?

M.D., Illinois.

To the Editor:—For the past two years I have been giving 1 mg. of vitamin K hypodermically to each expectant mother when she goes into labor and also 1 mg. of vitamin K hypodermically to each newborn infant shortly after birth. Is this of any nutritive value and are these dosages correct? Is there any danger in this procedure? Recently detail men have said that vitamin K is now prepared in 5 mg. ampules of 1 cc. each and that this is the proper dose for the type of case described.

M.D., Texas.

Answer.—1. Toxic reactions have not been reported from 2 mg. of menadione daily. It is unlikely that it will be of any benefit if the prothrombin is normal.

The amounts of A and D indicated are well below the toxic level (Park, E. A.: The Therapy of Rickets, The Journal, Aug. 3, 1940, p. 370. Tumulty, P. A., and Howard, J. E.: Irradiated Ergosterol Poisoning, *ibid.*, May 16, 1942, p. 233) and should not produce adverse effects in the case described in the query. However, the usual preventive dose of vitamin A is 5,000 U. S. P. units daily, being increased to 50,000 daily if evident deficiency exists. One thousand U. S. P. units of vitamin D daily should be adequate for either prevention or treatment in this case.

2. It has been shown beyond any question that vitamin K will correct the hypoprothrombinemia which develops in newborn babies (Quick, A. J.: Vitamin K for the Newborn, The Journal, March 21, 1942, p. 999) and is probably effective in reducing the incidence and severity of hemorrhages in these babies (Hellman, L. M., and Shettles, L. B.: *South. M. J.* **35**:289 [March] 1942. Williams, R. E.: *Canad. M. A. J.* **52**:397 [April] 1945).

The dosages are correct. It may be desirable to repeat the dose for several days in the babies (Vitamin Deficiencies, The Journal, June 22, 1946, p. 667). There is no known danger from the procedure.

Harm would probably not result from using 5 mg. doses. Amounts many times this large have been given to adults for considerable periods with insignificant toxic reactions (Allen, J. G.: *Am. J. M. Sc.* **205**:97 [Jan.] 1943. Shapiro, Shepard, and Richards, R. K.: *Ann. Int. Med.* **22**:841 [June] 1945).

DERMATITIS FROM PLAYING CARDS

To the Editor:—What chemicals in the finishing of playing cards might produce a contact dermatitis?
John T. Leland, M.D., Mill Valley, Calif.

Answer.—The ordinary playing cards are made of paper and stiffened with sizings. Sizings may be any of the natural or synthetic resins or such substances as sodium silicate. Any of the synthetic resins, if they are not completely cured, may cause sensitization dermatitis. Of the natural resins, rosin is the best known sensitizer. Sodium silicate, water-glass, has not been reported as the cause of sensitization dermatitis.

Within the past few years there have appeared on the market washable playing cards which are made of synthetic plastics. If these are incompletely cured they may cause dermatitis, just as may the synthetic resin sizings. In instances in which the dye comes off the playing cards, it is possible that some one may be sensitive to such dyes.

To contract dermatitis from playing cards would be unusual, because contact dermatitis rarely, if ever, occurs on the palms and palmar surfaces of the fingers (places coming in contact with the cards) because of the many layers of cornified epithelial cells covering the true skin in these areas. A diagnosis of dermatitis due to handling playing cards would have to be corroborated by positive patch tests with the playing cards.

ALOPECIA AREATA

To the Editor:—A man aged 44 sought medical care in November 1944 because of a feeling of unusual fatigue and lack of stamina. His doctor prescribed intravenous thiamine hydrochloride injections, daily applications of methyltestosterone, amphetame sulfate (5 mg. twice daily) and vitamin C. About the middle of January 1944 (after about twenty-five applications of methyltestosterone, fifteen amphetame tablets and a number of thiamine injections intravenously) the patient awoke one morning to find his pillow covered with loose hair. On rubbing his face he could feel the stubble of his beard come loose in his hands. After this shocking episode he continued to lose hair from his entire body. In one week there was a complete total alopecia. Since then the patient has been treated by a dermatologist, who prescribed a high acid ash diet and administered roentgen treatments to the scalp (75 roentgens) and grenz ray treatments. He has also received twelve injections of chorionic gonadotropin and a variety of tonics and shampoos, all without effect. Repeated laboratory tests have been normal, including serologic tests for syphilis. The loss of hair has affected the patient's mental state. He borders on desperation unless some relief or hope of relief can be given. Chemical substances which may cause alopecia have been ruled out. Advice as to treatment will be appreciated.
M.D., California.

Answer.—The patient described in the query has developed a universal alopecia areata. The cause is unknown. The earlier therapy given for the fatigue undoubtedly is not related to the loss of hair. The treatment should be both general and local as well as psychiatric. Wearing a wig helps the patient's morale. The use of tonics and B complex preparations has been recommended. The blood should be examined for the need of hematinics, and any other abnormality of the body should be sought for and corrected. Thyroid has been recommended, as well as agents which are antispasmodics. Local therapy usually includes one or several irritants, but these cannot be employed in this case because of the widespread nature of the ailment. The scalp alone could be treated with them. Liquefied phenol is applied over small areas and quickly neutralized with alcohol.

Generalized exposure to ultraviolet light may be useful in suberythema doses and somewhat larger doses for the scalp. Filtered x-rays to the cervical and other parts of the spine may be tried. The prognosis is poor in these generalized alopecies, especially in a man of middle age.

TENTORIAL TEAR

To the Editor:—How is a tentorial tear resulting from a birth injury diagnosed; and what are the possible sequelae? A diagnosis of "possible tentorial tear" was made at birth in a baby who is now 8 months old. While the entire vault of the cranium has not ossified, the baby appears normal except for an apparent lack of energy.
Captain, M. C., A. U. S.

Answer.—A positive clinical diagnosis of a tentorial tear is not possible. Such a tear of and by itself is not important, but the hemorrhage and associated cerebral damage may be. The only way in which this can be evaluated is by close observation and examination for evidence of cerebral involvement. The longer a child continues to "appear normal" without evidence of cerebral injury, the less likely does any serious injury at birth become.

TYPHUS IMMUNIZATION FOR PAN AMERICAN HIGHWAY TRIP

To the Editor:—Is it advisable to immunize a person going to Mexico, Central America and South America along the Pan American highway against endemic typhus, epidemic typhus or both?
Regina S. Greenebaum, M.D., Chicago, Ill.

Answer.—A person contemplating a trip to the areas mentioned in the query should be vaccinated against epidemic, or louse borne, typhus. Vaccination against endemic, or murine, typhus is not considered necessary.

CHICKEN PICKER'S DERMATITIS

To the Editor:—Several people who are employed at chicken picking have had an eczematoid type of dermatitis involving especially the hand and arm nearest the line of chickens. Please discuss this type of occupational disease.
John R. Morrison, M.D., Carroll, Iowa.

Answer.—Dermatitis among the handlers of chickens and other types of fowl is not uncommon.

Animal scabies may be contracted from infected domestic fowl. Animal scabies appears as pinhead size papules on the arms, thighs, groin or trunk and sometimes on the face. It may develop in a few hours to two or three days after contact and usually disappears in about three weeks after contact ceases.

Gamasoidosis, or fowl mite disease, is caused by Dermanyssus avium and gallinae. The lesions in man resemble urticarial papules and occur on the hands, forearms, and exposed portions of the neck, chest, and shoulders, and may also involve the face and scalp.

Fowl mites are prevalent on chicken farms. Persons who clean out the coops and those who handle the fowl are attacked by them. The chicken mite Laelaps stabularis may live in stables and attack horses, dogs, and stable men. The parasite may sometimes be seen as dark moving specks on the skin. They do not burrow, but nest in the sweat and sebaceous ducts which gape and become inflamed. This is followed by erythematous exudative folliculitis.

The prevention of the disease consists in wearing impervious sleeves, aprons, and rubber gloves. By applying insect repellents to the workers' clothes and exposed skin and spraying insecticides on the fowl, it may be possible to prevent the disease.

Mixtures of such insecticides and repellents as pyrethrum, DDT, dimethylthalate, Navy insect repellent #448, Indalone, or Rutgers #612 may be used in ointment bases on the skin and in solutions, emulsions or dusts for spraying the fowl.

GASTROINTESTINAL DISTURBANCE FOLLOWING MAPHARSEN INJECTION

To the Editor:—The question was asked in Queries and Minor Notes in The Journal, Sept. 14, 1946, page 117, whether there is anything to prevent a gastrointestinal disturbance arising from mapharsen administration. I agree that in a small percentage the psychic factor may play a role. However, in several large clinics which are devoted almost exclusively to the treatment of the Negro race I have seen numerous reactions in which the psychic factor is minimal. I believe that the odor of the drug plays a more prominent role in the gastrointestinal reactions. I have been using ethylaminobenzoate lozenges, following a recently published suggestion. The technic is as follows, with a slight modification: The patient places on the tongue two lozenges, each containing 1/10 grain (65 mg.) of ethylaminobenzoate, one-half hour before the injection is given. This is followed by one lozenge one-half hour after the injection is given. The purpose is to anesthetize the taste bulbs on the tongue. The results have been satisfactory, and few patients have complained of gastrointestinal reaction. I agree that other factors may be contributory.
Meyer L. Niedelman, M.D., Philadelphia.

To the Editor:—In regard to the item in Queries and Minor Notes entitled "Gastrointestinal Disturbances Following Mapharsen Injection" which appeared in The Journal, Sept. 14, 1946, page 117, may I suggest that, while treating a considerable number of servicemen overseas in a venereal disease clinic where for a time we employed mapharsen daily on a twenty day schedule of rapid treatment, this problem frequently arose. Two procedures were adopted which for the most part eliminated the distress of gastrointestinal disturbances in patients who had such reactions: routine administration of atropine sulfate 1/150 grain (0.4 mg.) given one-half to one hour prior to mapharsen therapy, and also the administration of 100 mg. of ascorbic acid three times daily. The latter we felt might in some degree protect against pruritus and the more remote possibility of dermatitis medicamentosa. We never knew whether it did or not, for such reactions did not develop in about 500 cases thus treated with rapid arsenotherapy. At any rate those with gastrointestinal disturbances became few and far between and were usually easily controlled.

ROENTGENOLOGIC DIAGNOSIS

Changes Resulting From Chemotherapy

ARTHUR C. CHRISTIE, M.D.
and
GEORGE M. WYATT, M.D.
Washington, D. C.

Roentgenologic diagnosis is based on the interpretation of variations in gross pathologic conditions as they are recorded on the roentgenogram or depicted on the fluoroscopic screen. There are certain criteria on which a fair degree of reliance may be placed in making diagnoses of infectious processes. Not only may these changes due to infection be recognized, but frequently sound judgments may be made in regard to the stage of the infectious process, and by successive examinations a fairly accurate idea may be gained of the progress of the disease and its probable outcome.

In the interpretation of roentgenologic observations in infections consideration must be given to the possible modifying effects of any therapeutic measures which have been used. Hitherto there was usually little difficulty in evaluation of the changes in the roentgenologic-pathologic picture resulting from therapy. This is no longer true since the advent of the sulfonamide compounds, penicillin and allied products. These drugs have not only profoundly modified the clinical aspects of infectious diseases but produced significant changes in the pathologic-anatomic manifestations, with a resultant change in their roentgenologic-pathologic appearance.

Never before has the body been called on to handle a situation in which there has been complete or partial arrest of an infectious process by the artificial killing or attenuation of the infecting organisms in situ. When all of the organisms have been killed, the resultant tissue responses and their roentgenologic manifestations present new phenomena. This is also true to a lesser extent when the organisms are abruptly attenuated and an active acute infection transformed into a low grade chronic state. These changes must be kept in mind and given careful consideration in the interpretation of roentgenologic observations. This is especially important in view of the common and widespread use of these new drugs in treatment against infections.

The following cases, with brief histories and accompanying roentgenograms, are presented for illustration and emphasis of the necessity for giving special attention to the diagnostic problems which may be encountered:

REPORT OF CASES

Case 1.—A white boy aged 4 was admitted to the hospital Oct. 15, 1944 during an attack of pustular chickenpox, the eruption of which appeared October 10. His temperature was 104 F. from October 12 to 15. On October 14 his right wrist had become swollen, red and extremely tender. He was placed on a regimen of parenterally administered penicillin on admission, receiving a total of 1,510,000 units over a period of eleven days. The acute tenderness and swelling began to subside on the second day, and within a week little tenderness remained. After the second week the only clinical residuum consisted of slight limitation of motion of the wrist, and this also had disappeared at the end of one month. The patient remained asymptomatic thereafter. A roentgenogram taken two days following the onset of symptoms did not show abnormality of the bones. There was edema of the soft tissue about the entire circumference of the distal ends of the radius and ulna, an observation which was considered consistent with early osteomyelitis. A film taken two days later showed a small area of osseous destruction with a break in the cortex, forming a cleft in the extreme distal ventral aspect of the radius. A definite diagnosis of osteomyelitis was made at this time. Figure 1 demonstrates the healing process of osteomyelitis. Eleven months following the onset only a scar remained at the site of the original disease. The bone which had grown beyond this scar appeared normal.

This case illustrates the manner in which the body handles osteomyelitis in which the organisms have been killed by adequate penicillin dosage during the early acute stage of the disease. The series of films presents a fairly complete and understandable picture. If, however, a single roentgenologic examination had been made at one of the stages in which subperiosteal bone was present, interpretation would have been rather difficult as based on the manifestations of osseous infection before the advent of chemotherapy.

Case 2.—A Negro woman aged 24 was well until about Dec. 28, 1944, when "tonsil infection" developed, as she was told by her physician. About two weeks following this infection a sudden severe, sharp, continuous pain developed in her right thigh just above the knee. This later extended up the thigh almost to the hip. About three weeks later she was still complaining of pain and tenderness. At that time her temperature was 99.6 F. She had a leukocytosis of 18,800 with 70 per cent neutrophils and a sedimentation rate of 27 mm. by the Wintrobe method. Roentgenologic examination of the right femur at that time showed no abnormality whatever. The patient was given 18 Gm. of sulfadiazine over a period of forty-eight hours. She did not report again until March 21, 1945. Roentgenologic examination of the right femur at that

---

Formerly Major, Medical Corps, Army of the United States (Dr. George M. Wyatt).

Read before the Section on Radiology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

From the x-ray section of Walter Reed General Hospital, United States Army, and the Radiological Clinic of Drs. Groover, Christie and Merritt.

time (fig 6 *A* and *B*) showed extensive motheaten osseous destruction involving the entire shaft of the right femur with elevation of the periosteum and a deposit of subperiosteal new bone. The white blood cell count was 10,000 with 73 per cent neutrophils and a sedimentation rate of 30 mm by the Wintrobe method. The patient refused to submit to a surgical procedure She was admitted to the hospital and 1,600,000 units of penicillin were given parenterally over a period of eight days. The pain and tenderness slowly disappeared, and at the end of two months she was practically symptom free. She was last seen Jan 18, 1946, at which time she complained of occasional pain in the right thigh but was otherwise well A roentgenogram taken at that time (fig 6 *C*) showed apparently complete healing of the osteomyelitis with decided thickening of the cortex of the femur

This case illustrates a more advanced stage of osteomyelitis, in which treatment was started later. The final appearance is more that of osteitis deformans than that of any other entity. The irregular osseous destruction and sequestration due to chronic osteomyelitis which was seen in earlier roentgenograms is not present.

Case 3—A white man aged 28 was first seen elsewhere in February 1944, at which time a diagnosis of nasal accessory sinusitis was made and he was placed on a regimen of sulfanilamide therapy for twelve days The sinusitis subsided On March 28, 1944 he was again seen with symptoms of dull aching pain in the anterior portion of the left thigh and with radiation of the pain to the knee The symptoms subsided with rest, but in August 1944 the pain returned and a small mass was noted in the upper posterolateral portion of the left thigh A roentgenogram made at this time was the basis for a diagnosis of osteogenic sarcoma (fig 2). There was an increase in the density of the mid shaft of the femur with almost complete obliteration of the medullary canal and proliferation of new bone about the periphery of the femur with spicules radiating into a soft tissue mass The appearance simulated that of osteogenic sarcoma There was, however, a sharply defined 8 by 13 mm. oval area of diminished density in the shaft at the lower margin of the lesion which did not have the appearance seen in cancer and represented a cortical abscess A surgical operation was performed Sept 12, 1944 and disclosed a soft mass composed of granulation tissue located adjacent to the posterolateral aspect of the mid femur, with a sinus tract measuring ½ inch (1 27 cm.) in diameter extending into the bone Free pus was present in the sinus tract The patient was placed on intensive penicillin therapy, and subsequent roentgenologic examination revealed that the new bone had begun to assume normal architecture

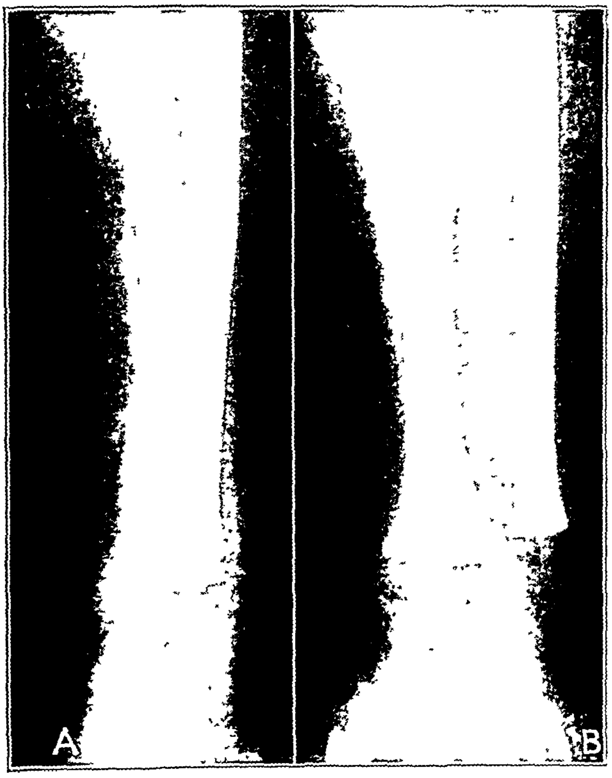

Fig 1 (case 1) *A*—There is a small deposit of new bone beneath the elevated periosteum *B* One and one half months following onset the subperiosteal new bone has assumed a nodular form A diagnosis of osteogenic sarcoma might be made if this were the only examination

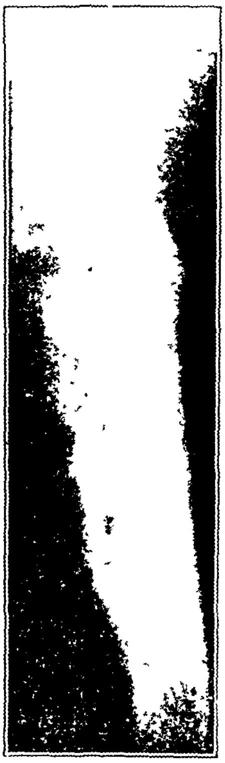

Fig 2 (case 3)—Lateral view of the femur

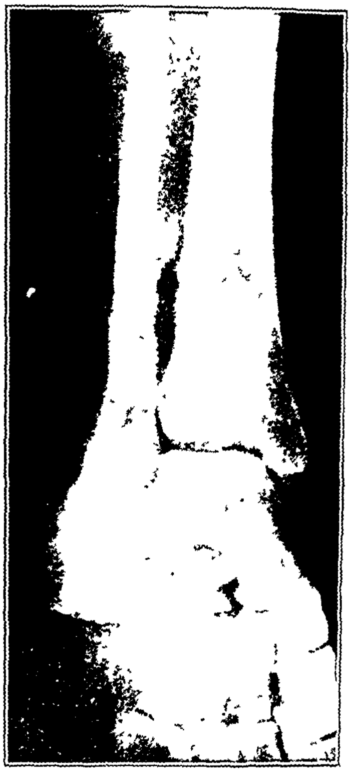

Fig 3 (case 5)—Oblique view of the distal part of the ankle and leg showing slightly irregular subperiosteal new bone with a knoblike projection of new bone toward the tibia This knob is higher in position than an exostosis, which it simulates Similar bony projections have been seen in 2 other cases similarly treated The general appearance is much like that of syphilitic periostitis and angioendothelioma

This illustrates a circumstance which will probably become increasingly frequent with the more widespread use of chemotherapy. The amount of sulfanilamide administered was sufficient to control the sinusitis, but larger doses and more prolonged administration are required to control infection of bone. It may be assumed that the osseous infection in this instance occurred at the time of the sinusitis, since there was no history of infection elsewhere. Symptoms of the infection of the bone did not occur, however, until after a lapse of over a month, and even then the process was an extremely low grade one The roentgenologic appearance is extremely bizarre, and the diagnosis of osteogenic sarcoma is understandable It seems reasonable to assume that the prolonged course and unusual roentgenologic picture is the result of definite attenuation of the infecting organism by inadequate chemotherapy.

Case 4.—A white man aged 24 was first seen elsewhere in October 1945 and was treated with sulfanilamide for an upper respiratory infection, which subsided About one month later he noticed pain and tenderness in the calf of the right leg; the symptoms were aggravated by walking. They increased in severity, and in December 1945 he was admitted to a hospital. A roentgenogram made at that time revealed essentially the same conditions as those seen on Jan. 14, 1946, when there was a sharply defined area of osseous destruction involving the lateral aspect of the cortex of the mid portion of the fibula for a distance of 4 cm. The lesion was expansile in character and had fairly smooth margins. In the center of the lesion there was a 1 by 8 mm. vertical spicule, which had the appearance of a sequestrum. The lesion as a whole, however, was not characteristic of any particular entity. In appearance it simulated fibrous displasia more than any other disease. The original diagnosis was possible bone cyst and the second, cortical bone abscess modified by chemotherapy.

The lesion was resected, and its histologic appearance was that of healing osteomyelitis.

CASE 5.—A white woman aged 44 first noticed pain and swelling of her right ankle in July 1945. The history did not disclose any preceding illness, infection or injury. She was seen elsewhere and treated with penicillin by mouth, sulfonamide compounds and diathermy. The exact dosages are not known, but from the patient's history the chemotherapy was neither intensive nor prolonged.

The symptoms abated, but after a few weeks they became progressively more severe. She reported to another physician, who requested the roentgenogram taken April 18, 1946 (fig. 3). A diagnosis of osteoperiostitis modified by chemotherapy was made, and she was admitted to the hospital. The Wassermann test was negative. The sedimentation rate was 16 mm. by the Cutler method. She received 1,475,000 units of penicillin parenterally over a period of eight days. She gradually improved and became practically asymptomatic two months after treatment.

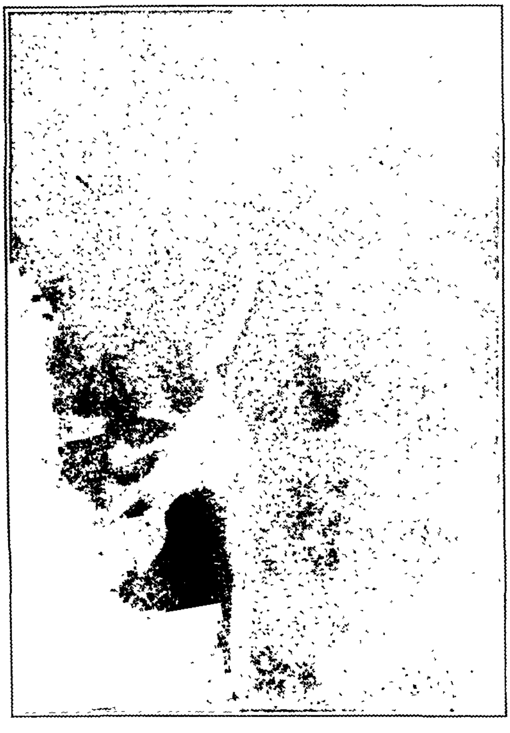

Fig. 4 (case 6).—Pyelogram taken in Germany on Aug. 11, 1944 showing enlargement of the upper pole of the right kidney and a slight pressure deformity of the upper calyx.

This case again illustrates the effect of inadequate treatment on infection; in this instance the method of treatment was the oral administration of penicillin, which requires such huge doses in order to be effective that the cost of the oral method is still prohibitive in most patients. The roentgenologic picture strongly resembles syphilitic periostitis except for the knob of bone projecting toward the tibia. This "knob" has been seen in 2 other cases similarly treated. Except for the knob the possibility of angioendothelioma should be considered.

Confusion has long existed in the differential diagnosis roentgenologically between tumor and syphilis in both bone and soft tissue. The same confusion now extends to any infection which has been altered by chemotherapy or penicillin.

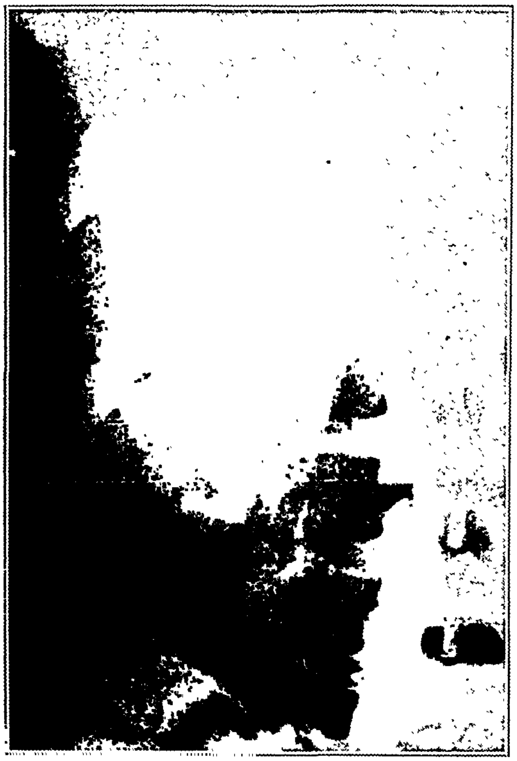

Fig. [illegible]).—Pyelogram taken Sept. 15, 1945 showing extensive pressure deformity of the calices of the right kidney from a mass either in or adjacent to its upper lateral portion. This film also shows a narrow line of diminished density along the adjacent margin of the liver which has the appearance of gas. The right kidney is fixed in position, and the right side of the diaphragm limited to about one-half the excursion of the left. The appearance is that of a perinephritic abscess, part of which is probably within the renal capsule, with gas in the soft tissues peripheral to the kidney.

CASE 6.—A white man aged 23 [1] was admitted Sept. 13, 1945 complaining of general malaise and a slight elevation of temperature to 99 F. in the evenings. Physical examination revealed a hard, fixed mass in the right upper quadrant of the abdomen. The patient had complained of abdominal pain on the right side intermittently for two years. Prior to this he had an attack of carbuncles which cleared spontaneously. At the time of, or shortly after, the carbuncles he contracted gonorrhea for which he received 200,000 units of penicillin. During part of the prolonged chronic illness the patient was a prisoner in Germany, at which time the first roentgenologic examination was carried out (fig. 4). A diagnosis was not made at this time. In the interval he lost 40 pounds (18 Kg.). The first diagnosis on subsequent examinations after the patient's return to the United States was renal tumor. The final diagnosis at the last examination (fig. 5) was perinephritic abscess, based on the presence of gas within the mass. A surgical operation was performed Sept. 18, 1945. A tremendously thick, hard mass of scar tissue was encountered in the region of the upper pole of the right kidney. When an incision was made through this scar tissue a large perinephritic abscess was opened and approximately 1,000 cc. of light green pus was evacuated.

---

[1] Lewis, L. G.: Diagnosis of Perinephric Abscess, S. Clin. North America 26: 357 (April) 1946.

This case illustrates the effect of inadequate penicillin therapy on an abscess of the soft tissue, the presence of which was unsuspected. Perirenal abscesses may be extremely chronic, but certainly two years is an unusually long duration. The abscess evidently began as a cortical abscess of the kidney, and its extremely slow growth resulted in a large, hard inflammatory renal and perirenal mass with decided distortion and compression of the renal calices simulating tumor or cyst

SUMMARY AND CONCLUSIONS

1. Roentgenologic diagnosis is based on gross pathologic variations from normal in tissues which are visible by roentgen ray.

2. Through experience, the changes produced by infection had become known and their various stages catalogued to such an extent that not only diagnosis but prognosis was possible.

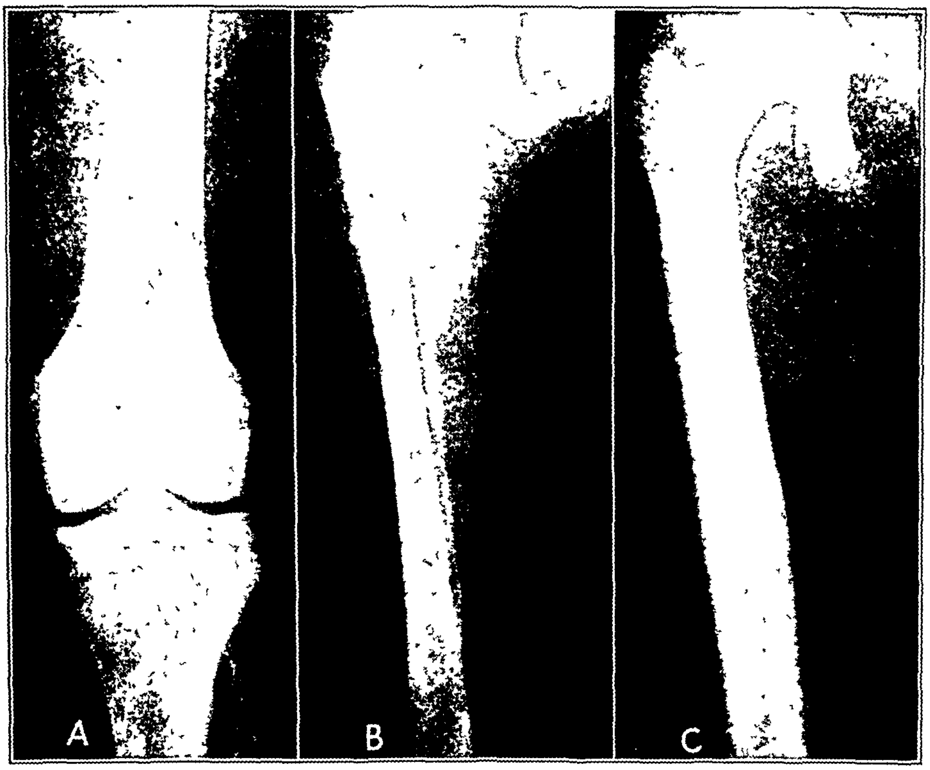

Fig. 6 (case 2) —*A*, there is an area of moth eaten osseous destruction involving a 6 cm length of the distal shaft of the femur, with new bone beneath the elevated periosteum extending upward from this area *B*, view of the remainder of the femur taken on the same date as *A* The entire shaft of the femur is involved by irregular destruction largely limited to the outer aspect of the cortex The whole is surrounded by subperiosteal new bone which is slightly laminated in character. *C*, seven and one half months later there is no roentgenologic evidence of active infection. The cortex is extremely thick, and its appearance simulates that of osteitis deformans

3. The sulfonamide compounds and penicillin have altered not only the clinical but the pathologic anatomic aspects of infection.

4. The most significant and previously unknown condition which results from inadequate treatment with these agents is that infection, the activity of which has been arrested completely or partially by artificially killing or attenuating the infecting organisms, leaves the tissues of the body to dispose of the resulting debris.

5. Body tissues have never been called on to handle such a situation. This altered reaction to injury of the body tissue by infection often simulates neoplasm and, as has been demonstrated, may be easily confused with cancer, syphilis and other conditions.

6. Chemotherapy is so commonly used that its effect must be kept in mind and investigated whenever an unusual roentgenologic or clinical observation is made.

ABSTRACT OF DISCUSSION

Dr L H. Garland, San Francisco: The antibiotics can sterilize a bone or soft tissue infectious process in midflight and leave the gross pattern of disease to confuse the clinical radiologist Drs Christie and Wyatt remind us once again that bacterial diagnosis is seldom possible by individual roentgenologic examination and that the newer drugs make even the diagnosis of active inflammation difficult. Their observations emphasize the fact that we are dealing in shadows of gross processes and that we tend to "overread" those shadows. Intelligent roentgenologic examination of diseased tissue (notably of bones and joints) requires that the interpreter have some information concerning the principal symptoms or clinical signs which happen to be present plus some facts on the medicaments administered to date Without these facts the most expert radiologist may be led to erroneous conclusions. I have seen a sequence of events similar to those noted in case 1 in a few cases of mild infection of the long bone treated with roentgen radiation They represent fairly prompt healing (and might have eventuated even without the small doses of irradiation given) The authors use the adjective "apparent" before the word "healing" in describing the final roentgenologic appearance in case 2 . This is important It is known that infection may be suppressed but not destroyed in some patients treated with antibiotics. The gross appearance becomes encouraging, only to break down at a later date The florid or productive type of osteoperiositic lesions seen in case 3 may simulate osteogenic sarcoma or vice versa I have seen cases of bone tumor in which needle or incisional biopsy gave no definite evidence of tumor I wonder if the authors would not diagnose case 6 as a carbuncle of the kidney, later followed by a perinephric inflammatory mass The interpretation of the radiolucent zone as gas is open to question The authors have probably seen some cases of mastoiditis in which sulfonamide or penicillin medication profoundly modified the roentgenologic appearance. To me this is one of the most perplexing phases of this question We are indebted to Drs. Christie and Wyatt for reminding us that criteria for the diagnosis of disease from roentgen shadows are, like so many other clinical phenomena, highly evolutionary and changeable but nonetheless simple and clearcut provided the basic factors of roentgenologic interpretation are constantly borne in mind

Dr Lowell S Goin, Los Angeles: I dissent from the statement that syphilis is the only lesion that can be confused with bone tumor In my experience angioendothelioma is always confused with infectious disease, and osteogenic sarcoma is frequently the same When the body is invaded by bacterial infection, it summons all its natural resources and alterations in the local and general behavior of the body begin at once. All the usual pathologic changes that accompany infection are found. The bacterial invasion overwhelms the patient, nature overwhelms the infection or the balance is such that neither is quite successful, and we encounter such states as long-standing chronic osteomyelitis If large amounts of antibiotics are given a patient and the bacterial infection is suddenly overwhelmed, we find we do not have the complete alteration in the roentgenologic appearance of the repair processes that we would expect, and this is what leads to confusion. There are only two changes in bone which can be recognized by roentgenologic examination—bone destruction and bone production. It is a recognition of these two changes and the summation of their variance on which the diagnosis of all bone disease rests. If some alteration occurs that changes the character of the destruction or production, prevents the production to the point where it would have been expected or limits the amount of destruction that occurs, then we have the confusing pictures that the authors have drawn to our attention.

Dr. George M. Wyatt, Washington, D. C.: I want to emphasize the main point we are trying to get across, namely to be on the lookout for these inadequately treated patients. You will notice that these patients were cured after they received adequate treatment, and what we must think about is the welfare of the patient. In regard to the kidney case, the diagnosis was renal cortical abscess followed by perirenal abscess. In regard to syphilis there has been for a long time confusion between the changes seen in syphilis, angioendothelioma and other bone tumors, whereas previously we only occasionally ran across a low grade infection which simulated both syphilis and tumor. Now with the modification of infections by chemotherapy we are going to see this similarity with increasing frequency.

ALLERGY TO VIRUS AND RICKETTSIAL VACCINES

I. Allergy to Influenza A and B Vaccine in Children

BRET RATNER, M.D.
and
SAMUEL UNTRACHT, M.D.
New York

One of the sound principles of allergy is that whenever the host is the recipient of a foreign substance, repeated invasions may result in a hypersensitivity to that substance. It follows, therefore, that the introduction of virus and rickettsial vaccines prepared from cultures grown in chick embryonic tissues must carry in its wake the phenomena of allergic reactivity. An intriguing aspect of the allergy induced by these vaccines is that the allergenic components responsible for these reactions are related to egg-chicken proteins, substances common to the diet.

Approximately 10 per cent of allergic persons are sensitive to egg and its related proteins. If the allergic population comprises 10 per cent of the total population, then 1 per cent of the general population is sensitive to egg in varying degrees. This sensitivity is spontaneously acquired through ingestion. With the advent of these newer vaccines, millions of persons have already had egg proteins introduced into them parenterally. It is possible that through this novel method of introducing a food protein, some persons may later become hypersensitive to egg-containing foods. Stull [1] has already demonstrated such an instance.[2]

The following general types of vaccines are considered in this paper: (1) yellow fever vaccine, grown on chick embryo tissues; (2) equine encephalomyelitis vaccine, grown on chick embryo; (3) typhus vaccine, grown on chick yolk sacs; (4) Rocky Mountain spotted fever vaccine, grown on chick yolk sacs (the last mentioned has also been made from combined yolk sac and chorioallantoic membranes—a so-called membrane vaccine), and (5) influenza A and B, grown in chick embryo chorioallantoic fluid.

ANAPHYLACTOGENIC PROPERTIES OF EGG-CHICK EMBRYO VACCINES

Well defined local and systemic reactions, terminating fatally in some instances, have been reported by Schoening [3] in horses after reinjection of equine encephalomyelitis vaccine. Similar observations were made by Wolfe and Trum [4] and by Graham.[5] Wolfe and Trum also observed apparently typical desensitization following recovery from anaphylactic shock. Because of allergic reactions, Schoening and his co-workers [6] suggested that vaccination be made by the intradermal route with small volumes of the vaccine. Satisfactory results have been reported from the use of this procedure.

Van der Scheer, Wyckoff and Bohnel [7] showed that guinea pigs can be sensitized with equine encephalomyelitis vaccine and fatally shocked on receiving a second inoculation. However, when Rocky Mountain spotted fever vaccine prepared from combined yolk and chorioallantoic membranes according to the method of Cox [8] was used for sensitization, they were unable to produce anaphylactic shock in the animals.

So far as ability to produce anaphylaxis in guinea pigs can be taken as a measure of capacity to sensitize man, it would appear that a vaccine grown on membrane can be administered with less danger of reaction than can a vaccine grown on entire embryo. Vaccines grown on membrane, such as typhus vaccine, contain less tissue than equine encephalomyelitis vaccine made from chick embryo, for even large amounts of the former did not produce a reaction, whereas a twenty-fold dilution of the latter was still an effective agent.

These experiments of van der Scheer and his associates indicate that vaccines grown on membrane (typhus and other rickettsia) are preferable to those grown on entire embryonic tissue, so far as sensitization is concerned. This fully corroborates the studies of Cox,[9] who also failed to induce sensitivity with Rocky Mountain spotted fever and typhus vaccines grown on membrane. Coulson and Stevens [10] showed that suspensions of washed rickettsial bodies contain egg antigens, but in a much lower concentration than that present in the egg yolk sac. Their studies indicated that such suspensions contain egg antigens in quantities which are near the minimum sensitizing dose.

Berge and Hargett,[11] employing yellow fever vaccine and crude extracts from normal chick embryos, found that in guinea pigs chick embryo extract from 10 day or younger embryos is weakly anaphylactogenic, while that from 14 day embryos is highly so. They suggested the use of younger embryos in preparing vaccine in order to reduce the anaphylactogenicity of these biologics.

From the Department of Pediatrics, New York University College of Medicine.

Further pertinent data on the anaphylactogenic properties of chick-egg vaccines is offered by Coulson and Stevens.[10] In general, the principal antigenic constituents in egg yolk sac vaccines, e. g., typhus vaccine and chick embryo vaccines, e. g., equine encephalomyelitis vaccine, are identifiable with antigens of fresh egg. Comparison of the anaphylactogenic activity of equine encephalomyelitis and typhus vaccines shows that, on the basis of protein nitrogen content, they are about equal in sensitizing capacity. On the other hand, the shocking capacity of equine encephalomyelitis vaccine is appreciably less than that of typhus vaccine. Coulson and Stevens attribute this to the heavier aggregation of the former vaccine's components, which serves to reduce the rapidity of absorption.

The sensitizing capacity of these two types of vaccines on a protein nitrogen basis, was found to be about one half that of egg white, and their antigenicity was related principally to the fresh egg white. These investigators found evidence that both typhus and equine encephalomyelitis vaccines contain antigens with specificity differing from that of egg white; but there was a lack of evidence that either vaccine contained antigen with specificity differing from that of combined egg white and egg yolk. Therefore, alteration of specificity of fresh egg proteins accompanying the organization of the protein into embryonic tissue during incubation could not be demonstrated.

These authors suggest that the results of their studies signify a possible hazard to potentially allergic persons and a definite hazard to those who are highly hypersensitive to egg proteins.

From the foregoing it would seem that chick embryo and embryonic fluids are highly antigenic and that vaccines grown on membrane and young embryo have a reduced anaphylactogenicity. Dr. Herald R. Cox[12] stated to one of us that if experience with reactions required it more of the antigenic material could be extracted.

HYPERSENSITIVITY REACTIONS TO VIRUS AND RICKETTSIAL VACCINES IN THE HUMAN SUBJECT

Eaton and Meiklejohn[13] in a series of 1,791 persons who received influenza vaccine noted but 3 cases of allergic reactions. In 1 patient a severe attack of asthma occurred within three hours after inoculation. A prior history of allergy was lacking. Urticaria developed in the second patient, and in the third, a probable urticaria.

Sulzberger and Asher[14] have reported 3 cases in which there is evidence for the assumption that yellow fever vaccine induced reactions: In 2 patients it resembled mild serum sickness, with urticarial and erythema multiforme eruptions occurring six and seven days, respectively, after injection; in the third there was a similar but accelerated reaction occurring in thirty-six hours. The cutaneous manifestations were accompanied by general malaise, pains in the joints, headache, fever, pruritus, nausea and vomiting. These observations indicate that this vaccine may potentiate hypersensitivity.

Swartz[15] has recorded a case of a severe constitutional reaction to a single immunizing injection of a mixed yellow fever and cholera vaccine occurring in a person aged 27. Less than five minutes after the injection the following symptoms ensued: blurred vision, labored breathing, nausea, vomiting, diarrhea, generalized urticaria and edema with increasing dyspnea, followed by unconsciousness. Symptomatic therapy with ephedrine and epinephrine resulted in a gradual abatement of symptoms, which finally subsided after six days. Two days later dyspnea and urticaria of a milder degree recurred, lasting for a period of two weeks. The patient's history disclosed that at 4 years of age he was fed large quantities of egg and egg white during an illness. From that time on, he was unable to eat eggs. He not only had an aversion to them, but the ingestion of the smallest amount of egg-containing food precipitated severe asthmatic paroxysms. He also was hypersensitive to other foods as well as to feathers.

Positive reactions to skin tests with allergenic preparations included a persistent and pronounced sensitivity to egg and chicken. Clinical tests performed on the patient with egg and chicken meat reproduced the symptoms previously described. His serum passively transferred sensitivity to the skin of normal recipients. Egg transferred 4 plus; chicken meat, 2 plus and yellow fever vaccine, 2 plus.

Since a virus is not known to be reaginogenic to produce cutaneous reactions of the immediate variety, Swartz has deduced that it was the culture medium fraction of the yellow fever vaccine that called forth the reaction. The fact that the skin test with cholera vaccine was negative contributes further to the conclusion that the allergic reaction must be related solely to the culture medium of the yellow fever vaccine.

Swartz expressed the opinion that so far as the egg white at all times caused stronger reactions than the chicken meat, this fact militates against the assumption of Berge and Hargett (given previously) that the age of the chick embryo has a direct bearing on the power to produce anaphylactic sensitization. If the assumption were correct, Swartz reasoned, the reactions would be related more closely to the chicken meat than to egg white.

This case vividly illuminates the importance of determining whether the recipient of this type of vaccine is hypersensitive to egg before proceeding with an injection.

Roth[16] has reported 9 cases of allergic reactions to typhus vaccine. Only 4 of the allergic reactors gave a history of allergy to egg, demonstrating that history alone is not a reliable criterion.

A typical case that Roth reported in a soldier aged 19 is here recounted. Immediately after the first injection of typhus vaccine the patient had extreme dyspnea, cough, weakness and substernal pressure. He had a temperature of 97.4 F., a pulse rate of 128 and a weak respiratory rate of 24. His skin was cyanotic and covered with an urticarial eruption; his face was edematous; his lungs were filled with asthmatic rales. The patient recovered in four days. Three days later, he was given 0.1 cc. of typhus vaccine, and a severe asthmatic attack followed immediately; but he did not have shock or cyanosis as before. He presented asthmatic rales, a temperature of 98.6 F., a pulse rate of 120 and a respiratory rate of 36. Recovery ensued in thirty-six hours. It is of interest that when he was profoundly affected, his respiratory rate was only 24, and later when his reaction was milder his respiratory rate was 36. This is an important criterion for the severity of an attack; the slower the respiratory rate, the greater the danger of asphyxial death. We have observed this repeatedly in guinea pigs in anaphylaxis.

Park[17] reported a reaction to the egg allergen in typhus vaccine. The patient, a British airman aged 35, was admitted to the station hospital in collapse, vomiting blood and presenting asthmatic breathing and generalized urticaria. He soon became comatose. Symptomatic treatment resulted in complete recovery by the next morning. He had received an injection of typhus vaccine fifteen minutes before the described reaction occurred. He related that he had been allergic to egg all his life. His usual reaction to egg was vomiting or, if it did not occur, edema of the lips, tongue and larynx, asthma and urticaria would follow. Never before had he vomited blood or passed into coma. Skin tests were positive to egg proteins by the scratch method and also with passive transfer tests. Park reported that his patient had received an inoculation of yellow fever vaccine about a year previously without any ill effects. Apparently he was sensitive to the yolk allergen.

A case reported by Plotz[18] concerned a soldier who had received cholera and typhus vaccine at the same time. About ten minutes afterward the patient had difficulty in breathing and almost immediately became cyanosed Artificial respiration was given, but the patient died about thirty minutes after the administration of the vaccines At autopsy, the lungs were found to be greatly distended, and they did not collapse on the opening of the chest cavity The autopsy report was that of a typical guinea pig variety of anaphylactic death

The case of Rubin[19] is of interest because a 19 year old soldier had a moderate allergic episode occurring one and one half hours after the inoculations of typhus fever and yellow fever vaccines He attributed the reaction to an egg yolk sensitivity which this person had since childhood Rubin showed conclusively that sensitivity to egg yolk was the dominant factor This bears out the observations of Coulson and Stevens that although egg yolk and egg white have antigens common to both, they also have antigens independent of each other The test results are of interest egg white ±, egg yolk 4 plus, chicken meat 0; yellow fever vaccine 2 plus, typhus vaccine 4 plus It should be recalled that yellow fever vaccine is made from chick embryo and typhus vaccine from egg yolk sac

Plotz attempted a study to determine whether cutaneous sensitivity follows the subcutaneous inoculation of typhus vaccine in man Skin tests were performed on 180 normal persons, as follows (*a*) before inoculation with typhus vaccine, (*b*) one week after second subcutaneous dose of vaccine (*c*) two weeks after third subcutaneous dose of vaccine, and (*d*) four weeks after third subcutaneous dose of vaccine All persons who showed cutaneous sensitivity were again skin tested six, eight and twelve weeks after the course of three doses of vaccine, 1 cc each, given subcutaneously on three successive weeks

Only 1 of the 180 subjects tested before the administration of typhus vaccine gave positive reactions to all the skin test antigens employed (typhus vaccine, egg white and egg yolk) The reactions were moderate—3 cm erythema and 1 cm induration (wheal) This subject tolerated three weekly inoculations of 1 cc each of typhus vaccine given subcutaneously without systemic reaction In none of the subjects in the control group (skin tested but not given injections of vaccine subcutaneously) did skin sensitivity develop However cutaneous sensitivity developed in 9 of 150 vaccinated subjects 1, later, to egg yolk and egg white 4 to vaccine alone 2 to vaccine and egg yolk and 2 to vaccine, egg yolk and egg white In all 9 cases cutaneous sensitivity was noted four weeks after the third dose The cutaneous sensitivity became negative after twelve weeks in 7 of the cases and diminished considerably in 2 In 2 persons the cutaneous reactions remained relatively unchanged twelve weeks after the third dose These 2 subjects must have been sensitized to a greater degree than the others for they reacted to egg yolk egg white and vaccine Despite the cutaneous sensitivity all the subjects sustained a subsequent subcutaneous injection of the full dose of typhus vaccine without systemic reaction

The suggestion of Beard Finkelstein and Beard[20] that repeated vaccination with equine encephalomyelitis vaccine may sensitize man is provocative but not too clearly defined by their data In 9 persons who were revaccinated they observed symptoms of cramppy stiffness" and indefinite muscular soreness in the lower portion of the thigh Local reactions were not present at the site of the injection A test for sensitivity was not performed Although allergic reactions can ensue from this vaccine as attested to in studies with horses (Schoening Wolfe and Trum and Graham) and in the guinea pig (van der Scheer and his associates) Beard and his co workers are not justified in labeling as allergic the reactions they noted As Coulson and Stevens point out equine encephalomyelitis vaccine is heavy its absorption is slow, and the recorded symptoms may be caused by such factors, particularly in view of the large, 2 cc dose injected Allergy due directly to reinjection is an important matter, and further investigations should be undertaken to clarify this phase of the subject

Two cases recounted to us are worthy of mention Ira Rubin[21] recalled a case that he observed while in the army, of a man in his early twenties in whom asthma and generalized urticaria developed within five minutes after the injection of 1 cc of influenza vaccine subcutaneously The symptoms of asthmatic breathing and urticaria gradually disappeared after four days Supportive and symptomatic therapy were administered This patient gave a history of sensitivity to egg since childhood One year prior to admission, he was given an injection of 1 cc of typhus vaccine Within fifteen minutes he was wheezing and had generalized urticaria At that time he was also confined to the hospital for four days and received several injections of epinephrine He was warned never to take any injection of a vaccine grown in an egg medium

The second case was that of a woman a member of the Women's Army Corps aged 25, who sustained a severe anaphylactic shock of a striking character She was given 1 cc of influenza vaccine at about 1 p m and was admitted to the hospital at 2 a m the following morning Her blood pressure was 40 systolic and a questionable diastolic reading She was treated for shock and was given epinephrine and ephedrine Wheezing and urticaria were absent The one sign was the tremendously lowered blood pressure She was discharged in one week with a blood pressure of 80 systolic and 50 diastolic A history of intolerance to egg was obtained Although not all the data could be recalled, the striking situation here is that this patient in all probability suffered a canine type of anaphylactic reaction, the cardinal symptom of which is a fall in systemic blood pressure

A study was undertaken by Stull[1] to determine whether vaccines grown on chick egg yolk sac contain sufficient egg proteins to cause severe systemic reactions if given to egg sensitive subjects In this investigation, skin tests were not performed directly on egg sensitive patients because of the danger involved in possible production of systemic reactions Serums from egg sensitive subjects were used, and the antigenic specificity and activity were shown by passive transfer Prausnitz Kustner reaction tests were performed on the skin of normal recipients

These tests revealed the presence in egg embryo vaccines of egg white and yolk antigens of such quantity and specificity that their injection might produce dangerous systemic reactions in egg-sensitive recipients Stull states that the recommended immunizing dose of typhus vaccine contains about two thousand times the dosage usually considered safe for intracutaneous skin tests in allergic subjects He concluded from the result of his studies that if egg sensitive persons were given injections of typhus vaccine similar to the lot used in his study, serious immediate systemic allergic reactions might ensue

In a patient aged 33, Stull relates that a delayed allergic urticarial local reaction occurred seven days after the first injection of 1 cc of equine encephalomyelitis vaccine (local serum sickness type of reaction[14]) Two weeks later a second injection of 1 cc produced a large local reaction within one hour (accelerated reaction indicating allergy) which lasted for six days Since that time this patient has had gastrointestinal disturbances with severe diarrhea following the eating of chicken or eggs The serum of this recipient contained antibodies to egg yolk and chicken embryo but not to egg white

Two additional cases were listed in the last *Quarterly Cumulative Index Medicus* by Sprague and Barnard,[22] who report alarming reactions in 2 patients at the time they received their original inoculation One had been given yellow fever vaccine and the other typhus vaccine After these episodes, a history of clinical sensitivity to egg was obtained in both Skin tests performed later proved that they were sensitive to egg proteins and to the vaccines

HYPERSENSITIVITY REACTIONS TO INFLUENZA VACCINE, A AND B, IN ALLERGIC CHILDREN

All the cases used in the present study were those of children ranging in age from 1 to 18 years. These children were known to be allergic, were suffering from asthma, eczema, urticaria and hay fever and had been completely studied for their hypersensitivities. Each child had been tested against three hundred or more allergens. A case was not used unless the child had been under observation for several months to several years. For this reason, all these subjects were familiar to us not only through the knowledge of their protein cutaneous hypersensitivities but also through intimate knowledge of their clinical behavior toward egg and other proteins.

Those patients who reacted positively by scratch test to dry proteins (Arlington) of the egg-chicken family were regarded as positive reactors to egg. The patients whose reactions to the egg proteins were doubtful and who gave a history of intolerance to egg were further tested with egg white, egg yolk and chicken (1:500 dilution) by the intracutaneous method.

Methods and Procedures.—All subjects were given injections of 0.02 cc. of undiluted influenza A and B vaccine.[23] The tests were read immediately and at varying intervals up to one hour. A skin test was regarded as positive if the test revealed an erythema measuring at least 3 cm. in diameter and a wheal measuring at least 1 cm. or more.

TABLE 1.—*Positive Allergic Reactors to Influenza (Type A & B) Vaccine*

Case, Age	Allergic Diagnosis	Allergic Sensitiveness			Vaccine Reaction to Intradermal Injection (0.02 Cc.)		Clinical Egg Sensitivity
		To Other Than Egg Protein	To Egg White	To Related Egg Protein	Local	Systemic	
1 D. D. 4 6	Eczema, Asthma, Hay fever, Urticaria	Inhalants, pollens, dust, bacteria	Moderate positive to intradermal (1:500), negative to scratch test	None	Definite wheal; erythema 4.0 cm	None	Ingestion of egg precipitated allergic attacks, nausea
2 L. D. 9 6	Eczema, Asthma, Hay fever	Inhalants, pollens, dust, nuts, fish, bacteria, condiments	Large positive reaction to scratch test, 5 cm. wheal with surrounding erythema	Egg yolk ovovitellin (scratch test)	Large wheal 6.5 cm. with erythema	Severe asthmatic attack 2 hrs. after test; lasted through night	Sensitive to egg since infancy; cannot tolerate any food containing egg; causes attacks
3 E. D. 5 3	Asthma, Eczema, Hay fever	Inhalants, pollens, dust, peanuts, nuts, fish	Moderate positive only to intradermal test	None	Wheal and erythema 4.0 cm	None	Cannot tolerate egg containing foods
4 B. F. 3 1	Eczema	Inhalants, pollens, cocoa, vegetables, fish	Moderate positive to intradermal test	Egg yolk (scratch test)	Small wheal and erythema 3.0 cm	None	Tolerates only hard boiled egg
5 W. F. 7 5	Eczema, Asthma, Hay fever	Inhalants, pollens, fish, nuts	Positive to scratch test	Egg yolk ovomucoid, duck egg, goose egg, chicken feathers	Positive moderate wheal and erythema 4.0 cm	None	Has avoided egg for several years
6 B. H. 14 10	Eczema, Asthma, Hay fever, Urticaria	Inhalants, pollens, wheat	Positive only *to intradermal* (1:500)	None	Positive moderate wheal and erythema 3.5 cm	None	Ten years ago, strongly positive to scratch test with *egg white*, yolk, ovomucoid, goose egg, duck egg, since then well immunized; eats egg *and is regarded as tolerant to* egg; reaction relates to residual skin sensitivity which sometimes *remains for years*
7 K. H. 9 1	Asthma	Inhalants, vegetables, chocolate, bacteria	Moderate positive *only to* intradermal	Suggestive reac*tion to yolk*, chicken and feathers	Positive mod*erate wheal* and erythema 3.5 cm	None	Tolerates egg
8 M. H. 15 3	Asthma, Hay fever, Emphysema	Inhalants, pollens	Definite positive to scratch test	Ovomucoid, feathers	Moderate positive wheal and erythema, 4 cm	None	Cannot tolerate egg or egg containing foods
9 P. L. 6 0	Asthma, Hay fever	Inhalants, pollens, dust, nuts, fruit	Definite positive to scratch test	Egg yolk, ovomucoid, feathers	Strongly positive wheal (4 cm.) and surrounding erythema	Received 0.5 cc subcutaneously following the intradermal reaction. An immediate reaction of generalized giant urticaria ensued which was *followed by* asthma; the generalized reaction persisted 2 days	Has been avoiding eggs since sensitivity was determined three years ago
10 R. S. 4 1	Asthma, Eczema	Inhalants, dust, pollens	Positive to scratch test and intradermal (1:20,000)	Yolk	Wheal (3.5 cm.) and surrounding erythema (1:10) dilution vaccine	None	History of exquisite sensitivity to egg, merest contact causes severe hives, angioneurotic edema, asthma and even stupor
11 B. W. 10 8	Eczema, *Asthma*, Hay fever, Urticaria	Inhalants, pollens, dust, milk, wheat, nuts, fish, vegetables, *fruit*	Positive only to intradermal (1:500)	None	Moderate positive wheal and erythema (3.0 cm.)	None	Ten years ago positive scratch test to egg white, yolk, ovomucoid; 4 years ago treated for egg intolerance; now eats egg and to all intents and purposes is nonsensitive at present

---

23. This vaccine was supplied to us by Eli Lilly and Company, through the courtesy of Dr. Horace Powell, and is prepared in the following manner. Ten day incubated eggs are injected with influenza virus types A and B. Thus seeded, the eggs are further incubated for forty eight hours, a large amount of virus developing in the allantoic fluid. By opening the embryo blood vessels, red blood corpuscles are allowed to mix in the embryonic fluids, which after they have been harvested and

(Footnote 23 continued on next page)

Control tests were done at the same time with solution of formaldehyde, 1:2000, and merthiolate, 1:40,000 in isotonic solution of sodium chloride.

Whenever a suggestive or positive reaction was obtained with the influenza vaccine in patients who had previously been negative by scratch test to dry egg and chicken proteins, further control tests were made by intracutaneous injection of 0.02 cc. of egg white, 1:500, egg yolk, 1:500, and chicken, 1:500.

I. *Positive Allergic Reactors to Influenza (Type A and B) Vaccine*

Of a total of 108 allergic children, 11 reacted positively to a test with influenza vaccine (0.02 cc. administered intracutaneously). In table 1 can be seen the detailed evaluation of these cases. In every instance in which the vaccine test was positive, the child also reacted to egg white protein. There was not a single positive reaction to vaccine demonstrated in the face of a negative reaction to egg white. This affords proof, therefore, that the positive reaction to vaccine must be related in large measure or, indeed, entirely to the presence of egg white protein in the vaccine.

In none of the remaining 97 children was a positive reaction obtained to the vaccine in the absence of a positive reaction to egg white.

In cases 2 (L. D.), and 9 (P. L.), systemic allergic reactions were induced by the injection of influenza vaccine. In the first instance, a large local reaction ensued, followed two hours later by an attack of asthma which persisted through the night. This was the only one of the 11 cases of sensitivity to egg white in which a systemic reaction developed from the small intradermal test dose of 0.02 cc. The child was known to be decidedly sensitive to egg white.

In the second case, in which the clinical and dermal sensitivity of the patient were less pronounced one-half hour after the intradermal test, which provoked a large local reaction but not a general reaction, a dose of 0.5 cc. of the vaccine was administered subcutaneously with due precaution and with epinephrine at hand. A generalized reaction occurred after this larger subcutaneous injection.

In cases 5 (W. F.) and 8 (M. H.) both patients reacted definitely to the scratch test with egg white vaccine and related egg proteins. These patients should be regarded as highly sensitive. In case 10 (R. S.), that of a girl who has had profound clinical allergic reactions from contact with egg, even to touch, an attempt to test with the full strength of the test materials was not made. She should be regarded as potentially exquisitely sensitive and perhaps would show a systemic reaction to the test in full strength.

Cases 6 (B. H.) and 11 (B. W.), are those of 2 children who ten years prior to this study were known to be extremely sensitive to egg white. Over a period of years both children were given egg white in gradually increasing doses, and both have tolerated egg in regular amounts in their diets for about eight years. Skin tests with egg white show that the two have only a residual dermal sensitivity to egg by the scratch test and only a moderately positive response by the intradermal route. The vaccine reaction was only moderate in degree. In the same category of moderate sensitivity, with probable absence of systemic reaction, can be placed cases 1 (D. D.), 3 (E. D.), 4 (B. F.), and 7 (K. H.); these patients did not react to the scratch tests and reacted only moderately to the intracutaneous (1:500 dilution) and moderately to the vaccine test.

II. *Suggestive Allergic Reactors to Influenza (Type A and B) Vaccine*

In this group of 39 patients, a doubtful reaction was obtained to the vaccine test dose. By doubtful we mean that there was not a definite wheal, and the erythema measured about 2 cm. Ten of these patients, all proved to be allergic when studied from the standpoint of other proteins to which they were found sensitive, gave suggestive reactions to various egg proteins. None of them could be regarded as clinically sensitive to egg.

TABLE 2.—*Types of Reactions to Virus and Rickettsial Vaccines*

		Allergic	Nonallergic; General
1	Onset..	Sudden and explosive	Delayed
2	Fever......	Absent	Moderate
3.	Chills..	Absent	Present
4	Local skin reaction to vaccine	Prompt wheaing or persistent erythema	Usually absent; when present, delayed, redness and swelling
5	Local skin reaction to egg proteins	Present, usually egg white	Absent
6.	Allergic manifestations	Various forms, usually urticaria, asthma and others	Absent
7	History of allergy to egg	Often present	Usually absent
8.	Clinical hypersensitivity to egg or chicken proteins	Usually present	Absent
9.	History of allergy to other substances	May be present	May be present
10	Eosinophilia	Often present	Usually absent

For example, of the 10 patients, 6 gave positive reactions to ovomucoid; of these 6, 3 showed suggestive reactions to other egg proteins, including egg white. Of the remaining 4, 1 reacted suggestively to egg yolk alone, 1 to egg yolk and egg white, 1 to egg white alone and 1 to chicken, egg yolk and egg white. None of these children gave a clinical story of sensitivity to egg.

Three children aged 7, 8 and 11 gave a history of intolerance to egg but demonstrated not even a suggestive reaction to egg protein. It is more difficult to explain the suggestive reaction to the vaccine in these cases, for the clinical sensitivity must have worn off entirely.

In the remaining 26 of this group that had a suggestive reaction to the vaccine, neither the egg test nor the history was positive. One cannot consider these reactions related to sensitivity to egg.

It must be assumed, therefore, that suggestive reactions to the vaccine are in some instances related to moderate sensitivity to egg and in other instances to sensitivity to some other ingredient in the vaccine mixture. In 4 instances, the reaction was just as large to the injection of solution of formaldehyde in the dilution of 1:2000 as it was to the vaccine.

---

pooled, are subjected to lowered temperatures. The virus, adsorbed to the red blood cells, is separated from the fluid by cold agglutination of the red blood cells, then allowed to elute under raised temperature. After centrifugation, the supernatant fluid contains active virus, suspended in isotonic solution of sodium chloride and concentrated to ten times the original virus concentration of the incubated egg fluids. Inactivation is effected with addition of solution of formaldehyde 1:2000, and preservation with merthiolate 1:40,000

We lack evidence in these studies that these children could tolerate the full dose of vaccine. We have every right to assume that they would not react adversely to such an injection. This phase will be the subject of a future publication.

In a parallel series of 28 normal children who did not present evidence of allergy in any form 8 also gave suggestive reactions to the vaccine, which reaction must be attributed to some nonspecific irritant or to a possible sensitivity to the solution of formaldehyde.

Whether sensitivity to influenza virus does exist is not known. It would appear for the present that only reactions to egg proteins are responsible for the positive reaction.

III. *Negative Reactors to Influenza (Type A and B) Vaccine*

This group of negative reactors to influenza (type A and B) vaccine comprises the largest number, totaling 59 cases. These children, as did those in the preceding group, all suffered from one or more of the cardinal allergic diseases; all were thoroughly studied and reacted to allergens other than egg.

Five children in this group gave suggestive reactions to egg proteins; 3, to proteins other than egg white, such as ovomucoid, ovovitellin and egg yolk; and 3, to egg white: 1 to egg white and ovovitellin, 1 to egg white and egg yolk and 1 to egg white alone. None of these children reacted to influenza vaccine; hence they must be regarded as so insignificantly sensitive to egg white as not to react to the vaccine. The remaining 54 children were negative throughout.

COMMENT

There are apparently two types of reactions that may ensue from the administration of virus or rickettsial vaccines. The first are the general constitutional reactions characterized by moderate fever, chills, malaise and delayed onset of symptoms. They occur in persons who may or may not have a personal history of allergy and who do not show eosinophilia. These reactions can vaguely be explained on the basis of reaction to a foreign protein.

The second type, with which we are here concerned, are the allergic reactions characterized by lack of fever, by immediate or explosive onset and by one or more of the varying allergic manifestations, such as asthma, gastrointestinal symptoms, angioneurotic edema, urticaria and other rashes. These patients often have an eosinophilia and a history of allergy to egg (see table 2).

Our study suggests that the positive allergic reaction to vaccine must be related in large measure, if not entirely, to the presence of egg white protein in the vaccine, for never was a positive reaction to the vaccine obtained in the absence of a positive reaction to egg white.

From a review of the literature there is little doubt that immediate, profound and even fatal reactions may ensue from the first injection of vaccine in a person exquisitely sensitive to egg white. In such cases our observations show that an intradermal inoculation of 0.02 cc. of the vaccine used as a preliminary test may induce a systemic allergic response. This is exemplified by case 2 (L. D.). It is imperative when a person reacts to the preliminary intradermal test in this manner that further administration of vaccine be withheld. Such instances are rare, however.

In case 9 (P. L.), although a large local, without a systemic, reaction resulted from administration of the test dose (0.02 cc.), when a larger dose (0.5 cc.) was administered subcutaneously one-half hour later, a profound generalized allergic reaction occurred. A large local positive intradermal reaction is evidence, therefore, for the need of exercising caution in the prophylactic administration of the vaccine. Further attempts to gather additional data on this point were not made because of the danger inherent in such a procedure.

When a local reaction is moderate in size, Plotz[18] has shown that the subsequent administration of three weekly inoculations of 1 cc. each of typhus vaccine can be tolerated without systemic reactions. This observation is fortified by cases 6 (B. H.) and 11 (B. W.) in our series; ten years previously these patients were decidedly sensitive to egg white, while at present only a moderate local reaction was obtained, indicating a waning sensitivity. It is reasonable to assume that this type of patient can tolerate a full prophylactic dose of vaccine.

Although related egg proteins apparently play a negligible role in this type of vaccine hypersensitivity, in all instances in which great sensitivity to egg white was evident, related sensitivity to egg protein was also present. This did not hold with equal regularity in instances in which there was residual or moderate sensitivity to egg, in most of which related sensitivity to egg protein was absent.

Of the 11 patients sensitive to egg white and vaccine, only 5 (cases 2, 5, 8, 9 and 10) could be regarded as sensitive enough to make circumspection and caution necessary in the use of the vaccine. Therefore, even though 11 of 108 patients (10.2 per cent) were sensitive to the vaccine, it appears that only 5 (4.6 per cent) were sensitive enough to warrant caution in administering the vaccine. Given an allergic group of children, one might therefore expect about 5 per cent to be sensitive enough to egg white to be decidedly sensitive to the vaccine. If the incidence of allergy in the general population is 10 per cent, then the serious egg allergenicity in the general population would be 5 per cent of 10 per cent (0.5 per cent or 1 in every 200 persons). If sensitivity to egg is more prevalent among children, as are all food sensitivities, then the figure of 0.5 per cent in the general population can be further reduced. This is in accord with the point of view of Plotz.

In order to safeguard these seriously sensitive persons, 1 or fewer in every 200 who are to receive vaccine, it is not alone sufficient to obtain a history of allergy to egg, for often this is vague, but a test dose of vaccine should be given before each and every prophylactic injection and perhaps also a test should be made with egg white. If both or either is strongly positive, the patient is seriously sensitive, and vaccine should be withheld. If a systemic reaction results from the test dose, vaccine should be withheld unconditionally. If only a moderate local reaction ensues, the vaccine can be given in three to six divided doses, spaced at one, two or three day intervals, with the concomitant administration of epinephrine (3 minims [0.18 cc.] of a 1:1000 dilution). These phases will be the subject of further investigation.

The 39 patients who gave only suggestive reactions to the vaccines also gave suggestive reactions to one or more of the egg proteins. These children for the most part were from 8 to 13 years of age and in all probability had a moderate or mild sensitivity, which at present is not of clinical significance. In a number of instances, some of these suggestive reactors were shown to be sensitive to the solution of formaldehyde and not to egg.

Lt. Col. Johnson F. Hammond, M. C.,[24] has stated: "Several severe reactions have been reported to the Surgeon General's office. The number of reactions known to have occurred is negligible in comparison with the number of doses of egg vaccine administered, now in the millions. Nevertheless, medical officers should be alert to the possibility of egg sensitivity in persons given typhus vaccine, yellow fever vaccine, or other prophylactic biologicals derived from eggs. If individuals suspected of being egg sensitive are given skin tests to confirm the diagnosis, egg vaccine material should be diluted 1000 fold and intradermal skin tests done by the injection of as small an amount as possible. If this test is negative, it may be repeated with a 1 : 100 dilution and should this be negative, with a 1 : 10 dilution. Undiluted vaccine may produce nonspecific irritative skin reactions. Desensitization is not recommended."

Several of the authors reviewed herein have expressed the opinion that the incidence of sensitivity in the army experience is smaller than it would be in civilian practice, particularly among children. It was with this in mind that the present study was undertaken in this highly potential group.

We believe that a history of allergy per se is not of any significance whatsoever, for allergic persons without specific sensitivity to egg proteins are not more likely to have a reaction from vaccine than is a nonallergic person. We are further of the opinion that a history of sensitivity to egg is of questionable value since in case 9 the patient who was highly sensitive to egg white, had a constitutional reaction to the injection of vaccine. When first studied by us for his allergy two years previously, the disclosure of sensitivity to egg was a complete surprise to his parents.

We agree with Colonel Hammond that all precautions should be taken before each and every administration of vaccine. From our experience we should like to offer certain suggestions and draw the following conclusions:

CONCLUSIONS

1. In a group comprising 108 highly allergic children who were studied completely for their allergy, 10.2 per cent were sensitive to eggwhite protein. However, only 4.6 per cent were sensitive enough to be regarded potential hazards for influenza vaccine administration.

2. Untested patients have been known to have a profound or fatal anaphylaxis from a first or subsequent prophylactic injection of influenza vaccine.

3. All persons should be tested intradermally with undiluted vaccine, using 0.02 cc. before administering each and every prophylactic dose.

4. If the test dose is negative or suggestive, the vaccine can be given with impunity.

5. If a moderate local reaction ensues, the vaccine can be administered with the added precaution of using 2 or 3 minims (0.12 to 0.18 cc.) of epinephrine simultaneously.

6. If a large local reaction is obtained, the vaccine can be given with the added precautions of using epinephrine just prior to the administration and giving the vaccine in divided doses at one, two or three day intervals. The vaccine can also be tried intradermally in several repeated doses of one-tenth the required amount. If this proves immunologically adequate, it may be the method of choice.[25]

7. If a test dose induces a systemic reaction, the vaccine should be withheld unconditionally.

8. Attempts should be made to rid the vaccine of as much egg protein as is possible in its manufacture.

9. A history of sensitivity to egg is not as reliable a criterion as an intradermal test with the vaccine.

10. Egg protein skin tests are necessary only for academic or research purposes, for it is proved by other observations, as well as by our own, that allergic vaccine reactions of any consequence are due entirely to the egg protein content of the vaccine.

11. Use of a virus or rickettsial vaccine for prophylaxis need not be feared if the single admonition is observed of preceding each and every prophylactic injection with an intradermal test dose of vaccine. This simple measure eliminates practically all hazard from the vaccine's use in the persons, approximately 0.5 per cent of the general population, who are hypersensitive to egg.

12. Use of vaccines is not dangerous to 99.5 per cent of the general population, which includes all the allergic persons who are sensitive to proteins other than egg and about 50 per cent of the persons moderately sensitive to egg. With further purification of the vaccine, even this small hazard can be further reduced.

13. The virus and rickettsial vaccines should be used with increased frequency in the civilian population, but the simple precautions herein outlined should be meticulously observed, to eliminate most, if not all, risk to the egg-sensitive person.

50 East Seventy-Eighth Street.

Prognosis in Coronary Disease.—Coronary disease persisted more than twenty years in 11 of my patients, more than thirty years in 2 of them. The record duration was fifty-two years in a lady who had her first attack of angina at the age of 30; she was leading a busy life at the age of 80, though still liable to angina whenever she walked. She died suddenly at the age of 82. It has long been known that quite extensive coronary disease is compatible with an active life and need not necessarily be associated with angina. In fact this used to be put forward as an argument against the view that angina is due to coronary ischemia. Coronary occlusion often antedates angina. It did so in 225 (22.5 per cent) of my cases. Yet before coronary occlusion can occur there must almost always be coronary disease. Moreover, a remarkably complete functional recovery is possible after a coronary occlusion. One of my patients played vigorous games after a coronary occlusion at the age of 39. He had a second attack at the age of 48 and, against advice, was playing tennis regularly two years later without any angina. Now at the age of 58 he is at work, plays golf and mows his lawn without cardiac symptoms. It is common for coronary disease to be entirely latent till sudden death takes place. Professor Hume of Newcastle tells me that since 1911 he has performed or attended postmortem examinations on 160 miners who had died suddenly and unexpectedly in the pit or in close proximity to it. The cause of death in each instance was coronary atheroma, and most of the men had been working regularly, without complaint, up to the moment of their fatal collapse. Only 40 had premonitory symptoms—Cassidy, Sir Maurice: Coronary Disease, *Lancet*, Oct. 26, 1946.

FOLIC ACID IN THE REHABILITATION OF PERSONS WITH SPRUE

GUILLERMO GARCIA LOPEZ, M.D.
Havana, Cuba
TOM D. SPIES, M.D.
Birmingham, Ala.
JOSE ARISTIDES MENENDEZ, M.D.
and
RUBEN LOPEZ TOCA, M.D.
Havana, Cuba

The observations of Spies and associates from studies made in the Calixto Garcia Hospital, Havana, Cuba, and carried out under the auspices of the University of Cincinnati, the University of Havana and the Institute of Nutrition of Cuba have made it abundantly clear that persons with sprue in relapse are profoundly benefited by the administration of synthetic folic acid. The acute manifestations of the disease subsided rapidly as the blood began its regeneration, and the alimentary tract tended to regain its normal function.[1] Although these cooperative studies are still in progress, we already have seen persons with sprue rehabilitated by means of folic acid therapy. The present report is confined to this aspect of our studies in 18 cases of sprue. The acute manifestations and the early response to folic acid in 9 of these cases have been reported.[1a] The present report includes and extends our observations in those 9 cases and includes 9 additional cases.

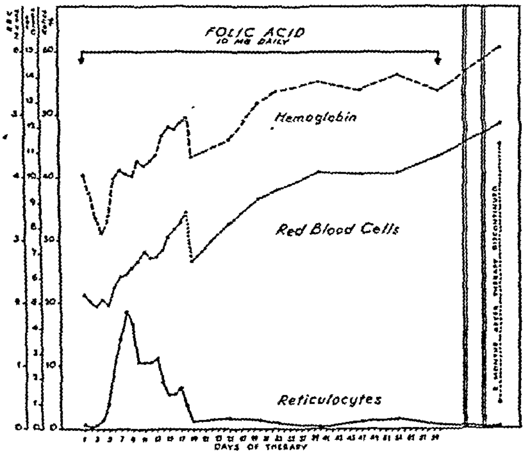

Fig. 1 (case 6).—Effect of folic acid on macrocytic anemia of sprue.

Eighteen patients were selected for study using the following criteria: 1. The patient must have macrocytic anemia. 2. The bone marrow must show the typical erythroblastic arrest seen in pernicious anemia. 3. The erythrocyte counts must be below 2.5 million. 4. The patient must be untreated, or he must not have been treated recently enough to interfere with our evaluation of the effect of folic acid. 5. He must have persistently low reticulocyte counts during the period of observation. 6. He must have glossitis and diarrhea characterized by fatty stools.

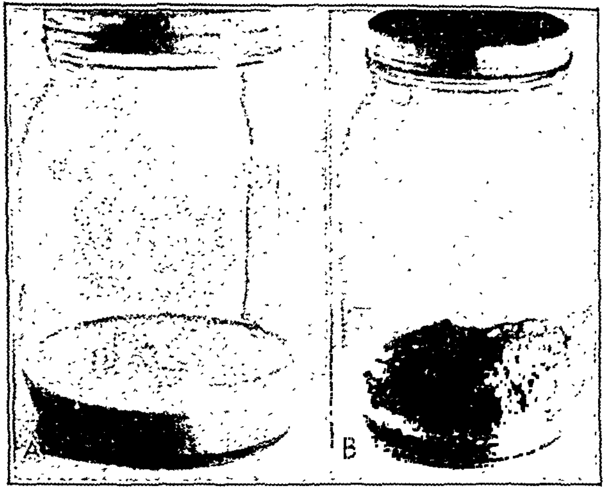

Fig. 2 (case 6).—*A*, liquid character of the stools on the day of admission to the hospital; *B*, stool seventy-two hours after the initiation of folic acid therapy.

Each patient selected was admitted to the hospital for preliminary examination, base line determinations and treatment in which the following plan of study was observed: From the time the patients were admitted their diets were rigidly controlled. Meat, meat products, fish and poultry were excluded, and only 1 quart of milk and 1 egg were allowed daily. All other foods were allowed to the extent desired. In each case a detailed medical and dietary history was obtained and a careful physical examination made. Daily hematologic examinations included white and erythrocyte

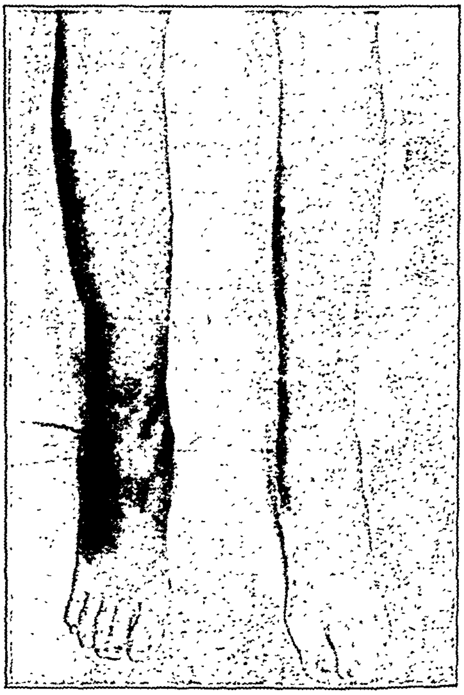

Fig. 3 (case 6).—Bilateral edema; note area of pitting on the right ankle following pressure with thumb.

The folic acid was supplied by Lederle Laboratories, Inc.

The expenses of this study were borne by grants from the Lederle Laboratories, Inc., and the Edward Mason Williams Fund and the Martha Leland Sherwin Fund.

University of Cincinnati Studies in Nutrition at the Calixto Garcia Hospital, Havana, Cuba, in cooperation with the Institute of Nutrition of Cuba and the University of Havana.

In the medical care of the patients included in this study we were assisted by many physicians who voluntarily aided us throughout the course of the study. In the special nursing and dietary care of the patients we were assisted by Miss Mariana de la Fuente, Miss Maria del Carmen Gonzalez, Miss Flora Villate, Miss Angela Pedraza, Miss Maria de las Angeles Perez, Miss Eva Averoff, Mrs. Eleanor Bennett and Miss Monette Springer, nurses, and by Mrs. Myrtle Neblett and Miss Jean Grant, nutritionists. The hematologic examinations were made by Mrs. Mary B. Koch, Miss Virginia Minnich and Miss Georgia Gwinner.

D.: Effect of Folic Acid on Persons with Macrocytic Anemia in Relapse, J. A. M. A. **130:** 474 (Feb. 23) 1946.

blood cell counts, hemoglobin determinations and reticulocyte counts. (Certified Trenner pipets were used for both the white and erythrocyte blood cell counts.) The hemoglobin content of the blood was determined in grams by means of a Leitz colorimeter, and the reticulocytes were counted in wet preparations by the use of a modified brilliant cresyl blue solution of Dameshek. From time to time cell volumes were determined on oxalated venous blood by means of Wintrobe hematocrit tubes. In each case bone marrow was obtained prior to treatment by sternal aspiration. Differential counts were made on preparations stained with both supravital and Wright-Giemsa stains. Gastric contents were collected before and after injections of histamine. Twenty-four hour stool specimens were collected daily in a single large glass graduated container. The stools were examined every day for appearance and volume. Each patient was questioned every morning concerning the number of bowel movements. Examination of the feces included tests for acidity, fatty acid determinations by the method of Labbe and Larue, bacteriologic examinations and examinations for parasites. Serum protein determinations were made in each case. In most cases blood calcium, phosphorus, potassium, amylase and lipase determinations were made.

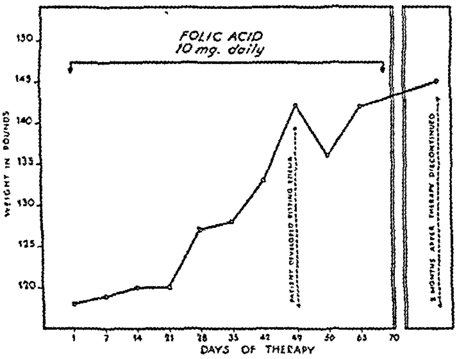

Fig. 4 (case 6).—Gain in weight by patient with sprue.

After base line determinations were obtained, folic acid was administered orally in water suspension between meals. It was prepared by mixing it to a smooth paste with 4 or 5 drops of cold water and then adding 20 cc. of cold water while the mixture was being stirred constantly. After the patient drank this material, a small amount of water was used to rinse the glass thoroughly, and he drank this also to insure his getting as much of the folic acid as possible. During the latter part of the study folic acid became available in tablets, and it was administered in this form. In the first cases studied (cases 1, 2, 5, 7, 8, 9 and 11) when we knew little about dosage, 100 mg. was administered twice daily. Subsequently, the dosage in these cases was reduced to 100 mg. daily and then to 25 mg. daily. From cases studied later (cases 3, 4, 6, 10, 12, 13, 14, 15, 16, 17 and 18) we learned that 5 to 10 mg. daily is just about as effective as the larger doses.

Dietary histories revealed that in every instance the dietary had not been completely adequate even prior to the onset of illness. The foods conspicuously lacking or eaten in insufficient amounts were meat, fish, poultry, eggs and milk. In all cases cereal foods, root vegetables and dried beans had been the foods used most commonly and *in the most liberal amounts. Following the onset* of illness, loss of appetite and soreness of the tongue had so interfered with the intake of food that in each case the diet of the patient was grossly deficient in all nutrients.

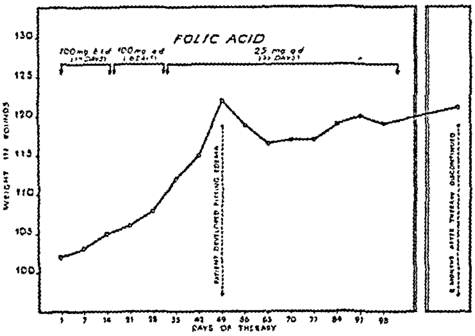

Fig. 5 (case 8).—Gain in weight by patient with sprue.

The major clinical symptoms on admission are shown in table 1.

The hematologic observations before and after therapy are shown in table 2. Many of the laboratory studies are still in progress. A complete report of determinations on bone marrows and stools subsequent to folic acid therapy will be published later. Suffice it to say at this time that both the bone marrow and stool determinations tend to revert to normal.

The typical clinical and hematologic response to therapy and the complete rehabilitation following therapy are illustrated in the following cases:

REPORT OF CASES

CASE 6.—*History.*—A. M., a white man aged 37, was admitted to the General Calixto Garcia Hospital on Nov. 30, 1945, with a history of loss of appetite, diarrhea, weakness, dizziness and soreness of the mouth and tongue of one year's duration. The family history and past history were noncontributory.

Until one year prior to his admission he had worked strenuously as a wood-cutter. He had a good appetite and ate large amounts of rice, dried beans and root vegetables. He disliked fruit and fresh vegetables and never ate them, and he seldom ate eggs or meat or drank milk. One year prior to his admission he began having severe diarrhea, which persisted for two weeks. During this time he had anorexia, weakness and loss of weight and was unable to work. His physician prescribed emetine, and the diarrhea disappeared. Although there was little improvement in his appetite or strength following the cessation of the diarrhea, he returned to work and continued to work for four months, at the end of which time he again

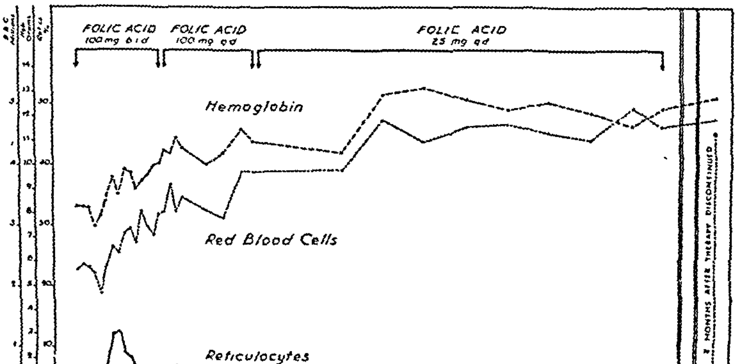

Fig. 6 (case 8).—The effect of folic acid on macrocytic anemia with sprue.

began having diarrhea. This time emetine failed to give relief. He had from four to six voluminous, foul-smelling, liquid or semisolid, yellow foamy stools a day which were accompanied by a sensation of flatulence and severe burning of the rectum. Since he did not desire food and thought that it aggravated his diarrhea, he restricted his diet to rice, bread and coffee. A few days after the diarrhea began he observed that his tongue was red and sore. A few weeks later he began having pain and paresthesias in the lower extremities. He grew progressively weaker, and for two weeks prior to his admission he had been unable to work. During the year he was ill he lost 32 pounds (14.5 Kg.) in weight.

Physical Examination.—Physical examination showed a well developed, undernourished, pale, weak, listless man who appeared extremely depressed. The skin was pale and generally dry and pigmented over the anterior surface of both legs. The tongue was slick except for many hyperemic papillae along the edges. The peripheral reflexes of the legs were uniformly diminished. The remainder of the physical and neurologic examinations revealed essentially normal conditions.

Laboratory Data.—Blood: Examination of the blood revealed the following: red blood cells, 2.13 million; hemoglobin, 10.1 Gm. (66 per cent) per hundred cubic centimeters; white blood cells, 5,200, and reticulocytes, 0.8 per cent. The mean corpuscular volume was 131 cubic microns, the mean corpuscular hemoglobin was 47 micromicrograms and the mean corpuscular hemoglobin concentration was 36 per cent.

Differential Bone Marrow Counts: In the bone marrow the percentage of cells was as follows: metamyelocytes, 17.0; myelocytes C, 13.5; myelocytes B, 1.5; band neutrocytes, 5.0; segmented neutrocytes, 30.0; basophils, none; eosinophils, 6.0; megakaryocytes and plasma cells, none; lymphocytes, 23.5; clasmatocytes, 3.5, and reticulum cells, none, for a total of 100 per cent. The number of megaloblasts was 3; early erythroblasts, 17; late erythroblasts, 35, and normoblasts, 79.

Gastric Analysis: A fasting specimen of the stomach contents gave a determination of 40 degrees free hydrochloric acid and 50 degrees total acidity. The reading thirty minutes after histamine stimulation was 95 degrees free hydrochloric acid and 100 degrees total acidity.

Serum Protein: The determination of serum proteins was: total, 5 Gm.; albumin, 2.2 Gm.; and globulin, 2.4 Gm., per hundred cubic centimeters. The serum cholesterol reached a total of 203 mg. and the serum cholesterol ester, 128 mg., per hundred cubic centimeters. Other determinations were: calcium, 12.0 mg.; phosphorus, 3.5 mg., and potassium, 10.0 mg., per hundred cubic centimeters. The serum amylase level was 110 units, the serum lipase, 0.3 (cc. of twentieth-normal sodium hydroxide per hundred cubic centimeters).

Stool Examination: Stool examination showed Trichuris trichiura, Necator americanus and Giardia intestinalis. Pathogenic bacteria were not obtained on culture.

Proctoscopic Examination: Proctoscopic examination showed normal mucosa without ulceration.

Progress.—On admission to the hospital the patient was given the diet previously described. After the base line studies were completed, he was given 10 mg. of folic acid a day by mouth. On the fifth day of therapy the reticulocytes rose to 4.0 per cent and reached a peak of 18.8 per cent on the eighth day. By the fourteenth day the red blood cells had increased to 2.84 million and the hemoglobin to 11.7 Gm. (76 per cent). At the time the patient was discharged, sixty-six days after folic acid therapy was initiated, the red blood cell count was 4.36 million, the hemoglobin 13.5 Gm. (88 per cent) and the reticulocytes 0.8 per cent. See figure 1 which shows the hemopoietic response.

The clinical improvement paralleled the hemopoietic response. Three days after therapy was initiated the patient stated that he felt stronger and said that he was hungry. He took all the food he was offered and asked for additional servings, whereas prior to treatment he usually refused everything on his tray except soup and coffee. Two days later he volunteered the information that his mouth and tongue no longer burned. A striking decrease in the diarrhea likewise occurred on the third day of therapy. That day he had only two stools which were soft, rather liquid, normal in color and not foamy (fig. 2).

Rectal burning ceased, as did the sensation of flatulence. Between the forty-second and forty-ninth days of treatment pitting edema of the ankles appeared (see fig 3) then subsided the following week. This clinical and hematologic improvement occurred despite the fact that he was not given antiparasitic therapy; examination of his stools subsequent to the administration of folic acid showed the presence of all the parasites found prior to treatment. By the time he was discharged on the sixty sixth day of therapy he had gained 27 pounds (12 Kg) (see fig 4). The day after he was discharged he returned to work as a wood cutter. Two months later he returned for follow up studies. At this time he was in excellent health. He was eating regularly the recommended diet which included liberal amounts of meat, eggs and milk. Bowel movements were occurring only once a day and were normal in volume, consistency and color. Although he had worked strenuously six days a week he had gained 3 pounds (1.4 Kg). Examination of the blood showed red blood cells, 4.87 million, hemoglobin 15.2 Gm (99 per cent), and reticulocytes, 0.4 per cent.

Case 8.—*History.*—P. E., a white man aged 63, was admitted to the General Calixto Garcia Hospital on Nov. 19, 1945 with a history of diarrhea, loss of appetite, weakness and burning of the mouth and tongue of five years duration. The family history and past history were noncontributory.

For a number of years his diet had consisted chiefly of potatoes, root vegetables, corn in various forms and from three to four eggs daily. He rarely drank milk and seldom ate beef and pork because he thought they caused gastric distress. Other than occasional gastric distress following the ingestion of beef and pork his health had been perfect until five years before admission to the hospital when he noticed a burning sensation of the mouth and tongue. Soon after this he began to have severe diarrhea. Sometimes he had thirty bowel movements a day which were usually preceded by severe colic. The stools were yellow in color and foamy. He consulted a physician who prescribed liver extract, which he took intermittently for three years, during which time he remained well. One and one-half years after he discontinued taking liver extract he again began to have diarrhea, and all the symptoms he had during his first illness reappeared. He lost his appetite, began having paresthesias of the legs, dizziness and tinnitus, and he became progressively weaker. After losing 20 pounds (9 Kg) he reported to his physician, who sent him to us.

Physical Examination.—Physical examination showed a well developed, pale, emaciated man who lay quietly in bed without apparent desire to move. The tongue was slick and shiny and was intensely red along the tip and edges. The remainder of the physical and neurologic examination revealed essentially normal conditions.

Laboratory Data.—Blood: Examination of the blood revealed red blood cells, 2.28 million, hemoglobin, 8.3 Gm (54 per cent), white blood cells, 7,900, and reticulocytes, 1.1 per cent. The mean corpuscular volume was 119 cubic microns, the mean corpuscular hemoglobin was 42 micromicrograms and the mean corpuscular hemoglobin concentration was 32 per cent.

Differential Bone Marrow Counts: In the bone marrow the percentage of cells was as follows: metamyelocytes, 17, myelocytes C, 17, myelocytes B, 3, band neutrocytes, 17, segmented neutrocytes, 26, basophils, none, eosinophils, 3, megakaryocytes, 1, plasma cells, 2, lymphocytes, 13, clasmatocytes, 1, and reticulum cells, none, for a total of 100 per cent. The number of megaloblasts was 4, early erythroblasts, 15, late erythroblasts, 12, and normoblasts, 44.

Gastric Analysis: A fasting specimen of the stomach contents gave a determination of 15 degrees free hydrochloric acid and 20 degrees total acidity. The reading thirty minutes after histamine stimulation was 65 degrees free hydrochloric acid and 75 degrees total acidity.

Serum Protein: The determination of serum proteins was: total 5.4 Gm, albumin, 3.6 Gm and globulin, 1.8 Gm, per hundred cubic centimeters. The serum cholesterol reached a total of 225 mg and the serum cholesterol ester, 180 mg, per hundred cubic centimeters. Other determinations were calcium, 10.8 mg.; phosphorus, 5.0 mg., and potassium, 13.4 mg., per hundred cubic centimeters. The serum amylase level was 98 units, the serum lipase, 1.3 (cc. of twentieth-normal sodium hydroxide per hundred cubic centimeters).

Stool Analyses: Examination of the stool disclosed that the p_H was 4.5 and the fatty acid, 12.3 cc. of tenth-normal sodium hydroxide (per 100 Gm. of moist feces). Stool examination did not show pathogens or parasites. Specific pathogenic bacteria were not obtained on culture.

Protoscopic Examination: The mucosa was edematous, congested, hypertrophic, slick and of a type compatible with a diagnosis of nutritional deficiency.

Progress.—On admission to the hospital the patient was given the diet previously described. After the completion of base line studies he was given 100 mg. of folic acid twice a day by mouth. On the sixteenth day, the dosage of folic acid was reduced to 100 mg. a day and on the thirty-first day to 25 mg. a day. (This was one of the first cases studied. We have since learned that 10 mg. a day would have produced the same response.) On the fifth day of therapy the reticulocytes began to rise and reached a peak of 12.5 per cent on the eighth day. By the fourteenth day the red blood cells had increased to 2.85 million and the hemoglobin to 10.0 Gm. (65 per cent), a net increase in red blood cells of 0.57 million and in hemoglobin of 1.7 Gm. Thirty days after the initiation of therapy the bone marrow was normoblastic. When the patient was discharged after one hundred and two days on folic acid therapy, examination of the blood showed red blood cells, 4.54 million; hemoglobin, 12.6 Gm. (82 per cent), and reticulocytes, 1.0 per cent. (See figure 6, which shows the hemopoietic response.)

Subjective improvement began on the third day of treatment when the patient volunteered the information that his appetite, strength and vigor had improved. By the sixth day the soreness of his tongue had disappeared, and the redness had begun to fade. By the twentieth day it was normal in appearance, and after forty-three days on therapy the papillae had completely regenerated. During the preliminary period of study he had been having from six to eight foul-smelling, yellow, frothy stools a day with a total volume of from 1,000 to 1,500 cc. They became normal in color, odor and volume, although they were

edema of the ankles, which occurred on the forty-ninth day of treatment and gradually subsided within two weeks, the clinical and hematologic improvement was uninterrupted. When he was discharged after one hundred and two days of therapy he had gained 17 pounds (7.7 Kg.) in weight (fig. 5). He returned to work in a copper mine the day after he was discharged from the hospital. When he returned for follow-up studies two months later, examination of the blood showed red blood cells, 4.80 million; hemoglobin, 12.8 Gm. (83 per cent), and reticulocytes, 0.6 per cent. Bowel movements were occurring only once a day and were normal in color, volume, odor and consistency. He had eaten regularly of the prescribed diet, which included liberal amounts of meat, eggs and milk. Despite having done heavy work in a copper mine eight and one-half hours a day for six days a week from the time he was discharged, he had gained 3 pounds (1.4 Kg.) and had remained asymptomatic.

COMMENT

Macrocytic anemias occur throughout the world. In the past, many clinicians have considered it essential to divide those cases due to a failure in diet (nutritional macrocytic anemia) from those due to a primary disturbance of the alimentary tract (addisonian pernicious anemia and sprue). Patients with macrocytic anemia with megaloblastic arrest of the bone marrow are studied carefully in our clinic before any attempt at clinical classification is made.[2] Tentatively the diseases of those having achylia after histamine injection are considered as addisonian pernicious anemia. Those having acid steatorrhea are considered as having sprue. The diseases of those having a dietary deficiency without achylia or steatorrhea we call nutritional macrocytic anemia. In an extremely large series of patients one finds persons whose symptoms are difficult to classify in any clearcut clinical syndrome. Indeed, the same patient when seen on different occasions may suggest different syndromes. It is generally considered that there is little essential difference between tropical sprue and nontropical sprue, or celiac disease, and our observations in the United States and in Cuba lend support to this contention. Moore, Bierbaum, Welch and Wright[3] have reported a case of nontropical sprue which responded to folic acid therapy, and Darby, Jones and Johnson[4] reported 3 cases of nontropical sprue which responded similarly.

---

[2] Moore, C. V.; Vilter, R.; Minnich, V., and Spies, T. D.: Nutritional Macrocytic Anemia in Patients with Pellagra or Deficiency of the Vitamin B Complex, J. Lab. & Clin. Med. 29: 1226, 1944.

Folic acid may be expected to exert an effect on macrocytic anemia in relapse in persons whose bone marrow shows megaloblastic arrest, irrespective of the presence or absence of steatorrhea, achylia, pellagra and the like. Unpublished observations by one of us (T. D. S.) show that thiamine, nicotinic acid and riboflavin lack therapeutic value in initiating regeneration of the blood in persons with these characteristic anemias and do not supplement folic acid therapy from the standpoint of regeneration of the blood. In patients with any type of macrocytic anemia a deficiency of these vitamins and iron frequently occurs at the same time, and in persons with sprue or nutritional macrocytic anemia there is also a high incidence of infection and parasitic infestations. These complications make research on the macrocytic anemias a difficult and tedious task. Before the introduction of folic acid there was not a known chemical substance that had any profound effect on the ultimate course of the sprue. The problem is now entirely different, and the present paper shows definitely that this substance is of profound importance in the rehabilitation of patients with sprue.

SUMMARY AND CONCLUSION

The present report shows that persons with sprue can be rehabilitated by the judicious use of synthetic folic acid. After the administration of the folic acid there was a prompt regeneration of the blood and a tendency of the alimentary tract to return to normal function. Despite the fact that antiparasitic therapy was not administered, the presence of pathogenic intestinal parasites did not prevent these persons from being profoundly benefited. (We make no claim that the folic acid in any way adversely affected the parasites, and all our examinations indicated that they continued to thrive in the intestinal tracts of our patients.) We do not recommend, in the day to day practice of medicine, that persons with sprue be given a deficient diet such as the one used in this study. In fact, we stress the desirability of prescribing a diet adequate in protein, vitamins and minerals. Of 18 patients rehabilitated, 5 are women who have returned to their full household duties. Nine of the 13 men have returned to work, 9 to their former jobs and 1 to a better job than he had prior to his illness. One of the 4 men (case 9) not working is a cripple who has never been able to work. The other 3, who are 75 years of age (cases 7, 15 and 16), had retired. These 4 patients, however, are able to care for themselves, whereas prior to treatment they had been bedridden and dependent on their families or friends for their personal care. Case 6 is representative of a man who returned to his former job as a wood-cutter. Case 8 is described in detail as an example of a man who returned to industrial work. Examination two months later has revealed that both are in excellent health. Neither one of them has missed a day's work since being discharged from the hospital.

Wilmington, Del.

The use of *p*-aminobenzoic acid (PABA) in the treatment of several of the rickettsial diseases has been reported recently. Following the experimental work of various investigators, Yeomans, Snyder, Murray, Zarafonetis and Ecke[1] gave the clinical results of the effect of *p*-aminobenzoic acid given orally to 20 patients with louse-borne typhus in Egypt. The course of the disease was favorably modified when treatment was begun early. Tierney[2] in an exceedingly well controlled study showed conclusively that the drug is effective therapeutically in tsutsugamushi fever or scrub typhus. He reported the cases of 34 patients with this disease between the ages of 21 and 45, 18 of whom received *p*-aminobenzoic acid. None of the treated patients died, whereas 3 of the 16 untreated succumbed. More convincing was the prompt drop in temperature and the subsidence of symptoms following the administration of *p*-aminobenzoic acid to the patients who recovered. A large dosage of the drug was given, and high levels were obtained in the blood. Minor toxic effects were observed in the patients receiving exceedingly high dosage. The optimum blood level was finally considered to be 30 to 60 mg. per hundred cubic centimeters.

Previously, experimental work by Anigstein and Bader[3] and by Hamilton, Plotz and Smadel[4] indicated that spotted fever rickettsias were even more susceptible to *p*-aminobenzoic acid than the typhus rickettsias. The first report of a case of spotted fever treated with this drug was by Rose, Duane and Fischel.[5] The patient contracted the disease on Long Island, N. Y., and the administration of *p*-aminobenzoic acid apparently exercised a beneficial effect. Maroney, Davis and Scott[6] reported a similar result in the first case of spotted fever so treated in Delaware. We are now reporting additional cases.

PREVIOUS STATUS OF DISEASE IN DELAWARE

In properly evaluating any new mode of therapy in a disease such as Rocky Mountain spotted fever, the preexisting status of the disease in the particular area concerned is most important. Dyer[7] in 1934 estimated

the mortality of the eastern type of Rocky Mountain spotted fever as 25 per cent; later the same author[8] gave the crude mortality for the disease for the entire country as 18 per cent. The Delaware State Board of Health[9] reports that in the ten year period from 1936 to 1945, inclusive, 50 cases were reported in Delaware. Of those 50 cases, 14 were fatal, a mortality of 28 per cent. A well defined difference in the fatality rate occurred in patients over the age of 40. There were 23 patients over the age of 40, of whom 12 died, a mortality rate of 52 per cent. There were 27 under the age of 40, with 2 deaths, or a mortality rate of about 7 per cent. We have analyzed the records of 31 cases (table 1) of Rocky Mountain spotted fever occurring in the Wilmington, Del., area from 1938 to 1946, inclusive. Twenty-one patients were not treated with *p*-aminobenzoic acid. The fatality rate is similar to that given previously for the entire state (table 2). Of the 21 patients, 5 died, or 24 per cent. There were 6 patients over the age of 40 (group *A*, table 1), of whom 3 died, or 50 per cent. Of the 15 patients under 40 years of age, (group *B* and *C*, table 1), 2 died, or a mortality of 13 per cent. It is evident, therefore, that in this particular area Rocky Mountain spotted fever is of a fairly severe type.

TABLE 1—*Summary of Thirty-One Cases of Rocky Mountain Spotted Fever in Delaware*

	Case	Age	Sex	Year	Day of Disease Admitted to Hospital	Days of Continuous Fever	Rash, Day of Disease	Day of Disease PABA Started	Total PABA Dosage, Gm.	Maximum PABA Blood Level, Mg./100 Cc.	Days of Fever After PABA Started	Proteus OX 19 Changing Titer	Result
Group A Patients over 40 yrs. of age not treated with PABA	1	18	♂	1938		15	3					Negative 1:1,280	Died

Group E patient over 40 yrs. of age treated with PABA	31	67	♂	1946	8	16	4	8	211.0	80.0	9	1:160 -1:800	Died *

* At autopsy, small granular kidneys indicating severe long standing renal disease were found.

TREATMENT WITH PARA-AMINOBENZOIC ACID

In this series of 10 patients treated with *p*-aminobenzoic acid, 9 under the age of 40 responded dramatically (group *D*, table 1). The records of these patients are very striking when compared to those of 13 patients (group *C*, table 1) under the age of 40 who recovered without receiving *p*-aminobenzoic acid (table 3). The average number of days of fever in the untreated patients was 17.5, as compared to 10.5 for the patients given *p*-aminobenzoic acid. The untreated patients averaged twenty hospital days; those treated, thirteen days. In the treated patients there was a decided clinical improvement twenty-four hours before the temperature started to drop. The temperature of patients given *p*-aminobenzoic acid dropped rapidly to normal within two to four days after treatment was begun, whereas in the untreated patients the temperature gradually came down to normal over a period of about sixteen hospital days. Coincidental with the lowering of the temperature the rash rapidly faded, and the patient made a prompt clinical recovery. The average day of disease on admission to the hospital was 7.2 days for the untreated patients and 5.5 days for those given *p*-aminobenzoic acid. The average day of disease on which therapy was begun was 7.6 days or about the same day of disease as that on which the untreated patients were admitted to the hospital. Composite curves of the maximum average daily temperature (chart 1) in the two groups is especially striking.

CLINICAL EXPERIMENTAL STUDIES WITH PARA-AMINOBENZOIC ACID

Para-aminobenzoic acid is known to be rapidly excreted by the body[10] and consequently the maintenance of a steady effective level in the blood necessitates frequent administration of the drug. In order to select the most favorable mode and schedule of therapy, studies were made of the blood levels and urinary excretion rates following administration of the drug in three different ways: (1) orally in aqueous sodium bicarbonate, (2) as 0.5 Gm. tablets of the sodium salt and (3) intravenously as the sodium salt.[11] The drug concentrations were determined by Bratton and Marshall's[12] sulfonamide procedure as modified by Eckert.[13] Although this method permits differentiation between free and coupled *p*-aminobenzoic acid as far as the amino group is concerned, it does not yield information on the extent of coupling on the carboxyl group to yield such products as *p*-aminohippuric acid, which according to Smith[14] occurs extensively.

[9] Delaware State Board of Health: Personal communication to the authors.

[10] (*a*) Zehender, F.: Ueber die Acetylierung von primären Aromatischen Aminen in Vivo und in Vitro, Helvet. chim. acta **26**: 1339, 1943. (*b*) Kirch, E. R., and Bergeim, O. J.: Determination of Para Aminobenzoic Acid, J. Biol. Chem. **148**: 445, 1943.

These studies have shown, in agreement with those of Zehender[10a] and Kirch and Bergeim,[10b] that within four hours following the administration of *p*-aminobenzoic acid by any of the three methods already mentioned essentially all of the drug has disappeared from the blood stream. During this time 70 to 80 per cent may be recovered in the urine; about 25 per cent of the material excreted is coupled on the amino group. In chart 2 the average blood levels obtained in two series of eight experiments are plotted as a function of time. One series of patients received 3 Gm. of *p*-aminobenzoic acid in a solution of sodium bicarbonate, the other 3 Gm of the sodium salt of *p*-aminobenzoic acid as six 0.5 Gm. tablets. These results suggest that, due to its slower absorption, more prolonged and steadier levels of the drug in the blood may be obtained with the tablet form and emphasize the importance of administration of the drug at least every two hours and perhaps more frequently if the bicarbonate solution is used. Considerable variations in the maximum blood levels following the oral administration of *p*-aminobenzoic acid, in bicarbonate solution and as the sodium salt in tablet form, were obtained. These variations probably result from individual differences in the subjects studied and may be related to the fluid balance (group *D*, table 1).

Parenteral administration of *p*-aminobenzoic acid may be desirable in the occasional patient who cannot retain the material by mouth or in the comatose patient who cannot swallow. As seen in chart 2, *p*-aminobenzoic acid is excreted rapidly when given intravenously. In the few instances when it must be given parenterally continuous intramuscular drip, as suggested by Woodward,[15] is probably the preferable method. A 25 per cent solution of sodium *p*-aminobenzoic acid in isotonic solution of sodium chloride is used. This solution is sterilized by filtration by a Seitz filter bringing the p_H to approximately 7 0 by the addition of small amounts of crystalline *p*-aminobenzoic acid to the solution of sodium *p*-aminobenzoic acid before filtration.

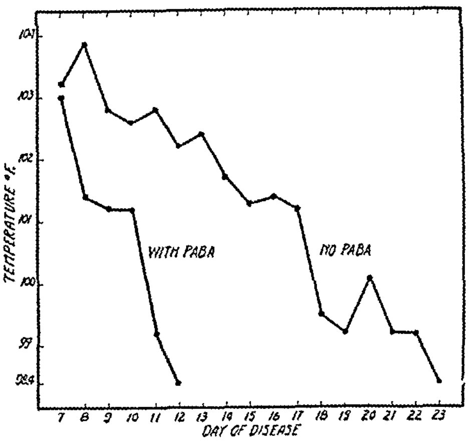

Chart 1—Comparison of average highest daily temperatures in 9 cases of Rocky Mountain spotted fever treated with *p* aminobenzoic acid, and in 13 cases not so treated.

DIAGNOSIS

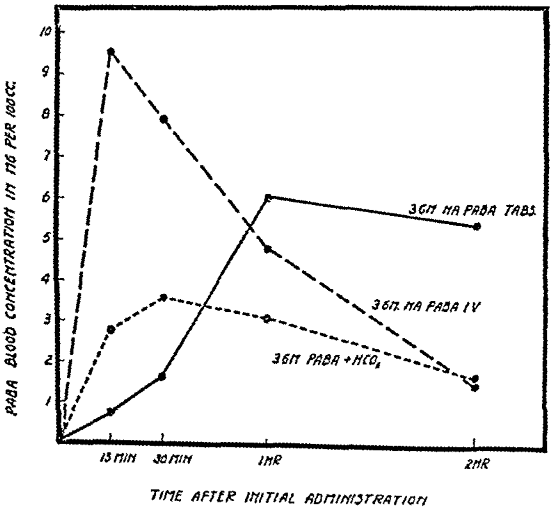

Chart 2—Result of eight clinical experiments in normal persons to determine blood levels when *p* aminobenzoic acid was given by mouth in 5 per cent sodium bicarbonate solution, when sodium *p* aminobenzoic acid tablets were given and when the sodium salt was given intravenously.

The great majority of the cases reported had all the criteria for diagnosis—tick bite, fever, typical rash and a changing agglutination titer for Proteus OX19. In a few cases the agglutination titer was not determined in the second week of the disease. In every such instance, however, the patient contracted the disease during the tick season in a locality known to be infected, and the rash was characteristic, occurring first on the wrists and ankles, then on the palms and soles and later spreading to the trunk. We consider that the diagnosis was correct in each case.

ILLUSTRATIVE CASES

Certain details of the records of 3 of the treated patients will serve to illustrate important points in the clinical use of *p*-aminobenzoic acid. Case 28 (chart 3) shows a secondary rise of temperature presumably due to a too rapid reduction in the dosage of *p*-aminobenzoic acid after the initial clinical response of the patient. Not only was the dosage decreased, but the interval of the doses was increased from two to three hours. Tierney [2] reported similar occurrences in scrub typhus when the dosage was reduced too soon. In this instance agglutination and blood level studies were not performed. The diagnosis, although not definitely proved, is almost certainly correct. A swollen tick was removed from the patient three days before she became suddenly ill with fever, headache and prostration, and on the fourth day a typical rash appeared.

Cases 29 and 30 are of interest in illustrating the importance of the control of fluid balance, especially the urinary output, in maintaining the *p*-aminobenzoic acid level in the therapeutic range. In case 29 (chart 4) when the twenty-four-hour urinary output was between 250 and 500 cc., the *p*-aminobenzoic acid blood level was 46 and 48 mg. per hundred cubic centimeters on a daily dosage of about 12 Gm. Later, when the output was 1,500 to 1,600 cc., the blood level dropped to 10 and 4 mg. with a higher daily dosage of 20 Gm.

Again in case 30 (chart 5) with daily doses of 36 to 54 Gm. of *p*-aminobenzoic acid, the blood level ranged only from 7 to 12 to 5 mg. until the urinary output was reduced from 1,300 cc. to 500 cc. The level then promptly jumped to 39 mg.; and the temperature, which had been falling slowly, dropped abruptly. Smith [14] reported the use of *p*-aminobenzoic acid in 29 cases of endemic (murine) typhus. The results were certainly beneficial but not so striking as in Tierney's [2] cases of scrub typhus or in the cases of Rocky Mountain spotted fever here reported. Smith gave 2 Gm. of the drug every two hours routinely without measuring blood levels routinely. If blood levels were estimated daily at the same time interval, preferably two hours, after the preceding oral dose of the medicament and if more attention were given to the urinary output in order to maintain a blood level between 30 and 60 mg. per hundred cubic centimeters, perhaps a clinical response might be obtained in patients with endemic typhus comparable with that obtained in those with scrub typhus and Rocky Mountain spotted fever.

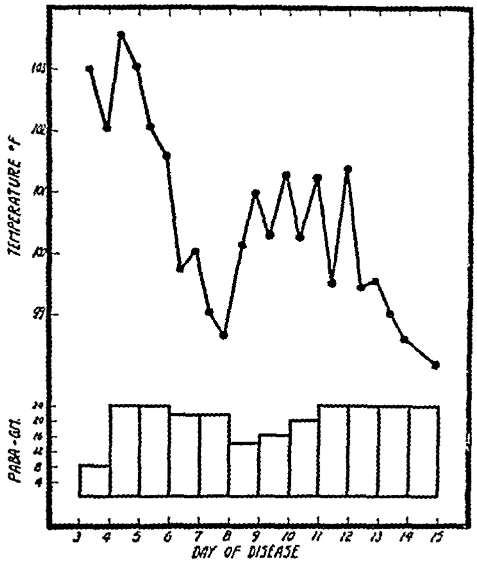

Chart 3 (case 28).—Secondary rise of temperature when dosage of *p* aminobenzoic acid was reduced too soon.

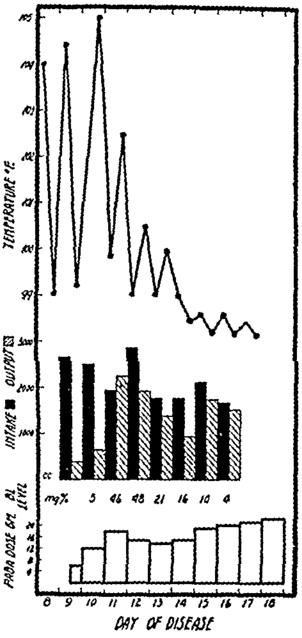

Chart 4 (case 29).—Showing a high blood level with a small dose of *p* aminobenzoic acid and low urinary output and a low blood level with a higher dosage of *p* aminobenzoic acid when the urinary output was increased

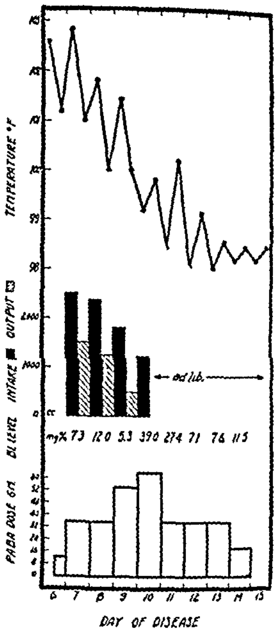

Chart 5 (case 30).—Showing difficulty in securing adequate blood level of *p* aminobenzoic acid until the urinary output was reduced.

The 1 fatality in our series was the only patient over the age of 40. He was aged 67 and refused admission until the eighth day of the disease, the fourth day of the rash. At this time he was mentally confused and had a blood urea nitrogen level of 60 mg. per hundred cubic centimeters. In spite of this he was able to swallow the *p*-aminobenzoic acid and absorbed enough to maintain a blood level of 48 to 80 mg. per hundred cubic centimeters for five days, when he died in uremia. At autopsy the kidneys were found to be small, granular and typical of long-standing renal disease. Evidently, therefore, he had had renal damage antedating the onset of his Rocky Mountain spotted fever. He also had had a previous myocardial infarction. This case may serve to illustrate the point that experimental work [16] has suggested—namely, that *p*-aminobenzoic acid retards or prevents the spread and proliferation of the rickettsias in the body but is not an antidote for any toxin already released and does not repair damage already done. Therefore the beneficial effect of the medicament in late cases is unlikely.

SUMMARY

1. Ten cases of Rocky Mountain spotted fever treated with *p*-aminobenzoic acid are reported and are compared with 21 control cases of Rocky Mountain spotted fever not treated with *p*-aminobenzoic acid.

---

[16] Greiff, D.; Pinkerton, H., and Moragues, V.: Effect of Enzyme Inhibitors and Activators on the Multiplication of Typhus Rickettsiae: Penicillin, Para-Aminobenzoic Acid, Sodium Fluoride and Vitamins in B Group, J. Exper. Med. 80:561-574, 1944. Hamilton, Plots and Smadel

2. All 9 treated patients under 40 years of age recovered. One patient over 40 years of age with complications due to cardiorenal disease died
3. In 21 untreated patients there were five deaths—2 in patients under 40, 3 in patients over 40 years of age.
4. The length of fever in untreated patients was 17.5 days as compared to 10.5 days for those given *p*-aminobenzoic acid.
5. Most of the treated patients showed dramatic clinical improvement shortly after treatment began.
6. The *p*-aminobenzoic acid was administered without complication.
7. Because of the rapid urinary excretion of the compound, oral administration at one or two hour intervals is required to maintain therapeutic blood levels.
8. Individual variation in blood levels requires the adjustment of dosage and fluid balance
9. The tablet form of sodium *p*-aminobenzoic acid produced more prolonged and steadier levels of the drug in the blood in clinical experiments on 8 volunteers

CONCLUSION

Para-aminobenzoic acid was found to be most effective in the treatment of 10 cases of Rocky Mountain spotted fever in Delaware.

Clinical studies suggest that the level of p-aminobenzoic acid in the blood is best kept in the optimum range of 30 to 60 mg. per hundred cubic centimeters by adjustment of dosage and fluid balance in each individual case.

TOXIC REACTIONS ACCOMPANYING PENICILLIN THERAPY

W J MORGINSON, M D
Salt Lake City

Since Fleming's[1] observations on the antibacterial action of penicillium in 1929, toxic reactions produced by and accompanying the clinical use of this medicament have constituted an important part of the extensive literature on penicillin. The observations by my associates and me are incorporated in the various papers[2] from Bushnell General Hospital; the papers by Lyons,[2b] Keyes[2c] and Morginson[2i] particularly discuss toxic reactions. The findings made at Bushnell General Hospital agree with those of other authors and will not be listed separately.

In the short time at my disposal, it will be impossible to discuss in detail all the reactions that have been enumerated as following penicillin therapy. These are listed in the various tables. This paper will present salient observations concerning each group of symptoms. The adverse symptoms produced by penicillin may be grouped and will be discussed according to its role as (1) direct toxin and primary irritant, (2) antigen, (3) therapeutic shock excitant and (4) indirect action on pathologic processes.

DIRECT TOXIN AND PRIMARY IRRITANT

Crude and commercial penicillin is not a direct toxin in concentrations permitting its therapeutic use. Fleming[1] was the first to show that subcutaneous and intraperitoneal injections and irrigations of large surfaces and of the conjunctivas had no ill effects. Subcutaneous injections in mice, rats and cats produced no sloughs, and blood concentrations to 5,000 units per cubic centimeter had no deleterious effects.[3] In mice, the toxic dose is about sixty-four times the effective dose as determined by subcutaneous injections of crude penicillin.[4] A wide variance in lethal doses for mice, ranging from 3,500 to 32,000 units, was observed when three hundred lots from fourteen manufacturers were tested.[5]

Human leukocytes remain active in 1,000 units per cubic centimeter for at least three hours.[6] Daily doses of 400,000 units in experimental animals produced no injury to kidneys, liver, bone marrow or brain[7] and low toxicity for tissue cells as measured by means of in vitro methods of tissue culture.[8] Apparently there is no disturbance of the peripheral blood or hemopoietic system, and penicillin can be used in the presence of pronounced anemia, leukopenia and agranulocytosis.[7b]

It has not been determined whether the minimal direct toxic action of penicillin depends on impurities contained in the corn mash or steep, chemicals used to remove pyrogens or other products in commercial penicillin, as little comparative work has been done on the toxicology of crystalline penicillin. Purification, apparently, reduces toxicity.[3b] The toxic action does in part depend on the cation radical, as intravenous toxicity in mice increased progressively with the use of the sodium, ammonium, strontium, calcium, magnesium and potassium salts.[9] Gottschalk and Weiss[10] stated that commercial penicillin is not a primary cutaneous irritant.

For practical purposes the possibilities of penicillin as a direct toxic agent are negligible[11] except, as will be noted, following its intrathecal use

ANTIGEN

Experimental evidence and clinical observation indicate that commercial penicillin and crystalline penicillin possess definite antigenic and allergenic properties.[12] These may be excited by impurities encountered in commercial penicillin, pyrogens, chemicals used to remove pyrogens and crystalline penicillin.[13] It is generally conceded that antigenic reactions are becoming less frequent as impurities are removed from commercial penicillin; the early, dark-colored products seemed to produce more frequent and violent reactions than the later, clearer solutions.[14] Cormia and colleagues, however, stated that no correlation could be observed between the color of commercial penicillin and toxicity.[15] Many of the impurities can be removed by Seitz filtration.[16] Reactions are probably due to impurities when different lots and products of different manufacturers fail to repeat symptoms or give negative reactions to sensitivity tests.[15b]

TABLE 1—*Reactions Produced by Antigen Properties of Penicillin*

1 Erythema blotchy, diffuse, morbilliform, scarlatiniform, flushing of face, dermatitis *medicamentosa, exfoliating* dermatitis	2. Urticaria sparse, mild, diffuse, massive, transient, acute, chronic, pruritic
3 Angioneurotic edema localized, lips, eyes, tongue, uvula, pharynx, epiglottis, larynx, diffuse, solid	4. Erythema multiforme, erythema nodosum, edema of joints, polyarthritis, painful adenopathy, myalgia
5 Malaise, headaches, generalized aching, chills, fever, nausea and vomiting, abdominal cramps	6 Dyspnea, pulmonary edema, acute syncope, shock
7 *Dizziness, vertigo, muscular* twitching, convulsions, loss of consciousness	8 *Euphoria and laughing,* psychotic depression, agitation, confusion, nervousness
9 Epistaxis, petechiae, purpura, regional angiitis	10 Eosinophilia, pseudoalbuminuria, hematuria, azotemia
11 Tingling in testes, epididymitis	12 Thrombophlebitis
13 Exacerbation latent trichophytosis, trichophytids, dyshidrosis	14 Photosensitization
15 Drug and serum sickness like syndrome	16 Precipitated latent epilepsy

Sensitization attributes of commercial penicillin have been demonstrated by positive intradermal reactions,[17] by indirect or passive transfer tests of Prausnitz-Kustner,[18] by precipitin reactions [13a] and, in guinea pigs, by Schultz-Dale tests.[19] Positive intradermal reactions,[20] Prausnitz-Kustner reactions [13d] and positive Arthus phenomena [13b] are observed with crystalline penicillin. Heterophil agglutinins have been reported increased by Lyons [2b] and not increased by Cormia.[15a] The latter author also stated that precipitin and passive transfer tests furnish variable results and that conclusive evidence of circulatory antibodies has not been demonstrated. Patch tests have elicited positive reactions to commercial penicillin [21] and to crystalline penicillin.[21a]

Sensitivity to penicillin may be manifested as immediate reactions and delayed reactions.[15a] The immediate reactions usually occur in persons with a known history of penicillin sensitivity or at least previous exposure to penicillin, although a small percentage of the population is primarily or spontaneously sensitive to penicillin.[22] It is doubtful if natural, inherited sensitivity, without previous exposure, exists, because contact may have been intrauterine or the patient may possess a general sensitivity to molds.[23] Herrell, Nichols and Heilman [7b] and others [24] have demonstrated the transmission of penicillin through the placenta from the maternal to the fetal circulation. Jadassohn, Schaaf and Wohler,[25] working with trichophytins, by the Schultz-Dale technic, concluded that fungi have a common antigenic factor in addition to antigenic factors peculiar to each species. Persons may be sensitive to penicillin because they possess a common sensitivity to all molds. Cormia [15a] and Lamb [18a] stated the belief that an exacerbation of a previous fungous infection or vesicular eruptions involving the feet, hands and groins following penicillin therapy may represent this common antigenic factor to molds.

Delayed or acquired sensitivity may be produced by repeated intradermal injections of penicillin [20] or by repeated local applications [10a] and is analogous to drug or serum sensitivity.[26] Sensitivity to penicillin may be of short duration or it may last for considerable periods, even months, and it is conceivable that it may be permanent.[13a] Toxic symptoms may not be noticed until several weeks following continuous injections.[13d] The antigenic potentialities may be latent, requiring lowering of allergic resistance and augmentation with other antigens to present symptoms.[27]

Penicillin sensitivity may be epidermal [28] or dermal,[15a] although the principal shock tissue seems to be the vascular system.[15a] Gottschalk and Weiss [10a] expressed the opinion that epidermal sensitizations do not predispose to dermal or vascular sensitization; however, severe systemic involvement was encountered in Cormia's [15a] patients following local application of penicillin. If local applications can produce generalized sensitivity, as seems possible, a word of caution should be made against the injudicious use of penicillin locally.

[28] Gottschalk and Weiss [10] Cormia and colleagues [15a]

Allergic symptoms following penicillin therapy are usually mild, of low incidence and transient. Several authors have recommended that treatment be continued after their appearance and have minimized their seriousness.[29] Others are more cautious and have emphasized that heed should be given to these manifestations, as persistence with treatment might lead to severe, alarming and serious reactions.[30] Wile [31] considered that severe angioneurotic edema and edema of the pharynx, larynx and lungs, known to accompany penicillin therapy, are serious and may be fatal complications. Lamb [15a] expressed the opinion that each patient should be questioned regarding history of allergy, history of previous penicillin sensitivity and history of trichophytosis or other fungous infections. When a patient is sensitive to crystalline penicillin, as may be shown by cutaneous reactions or suspected when different lots or products of different manufacturers produce symptoms or give positive reactions, continued therapy should be used with extreme caution or only after desensitization, as severe reactions may be anticipated.[30b] Kolodny and Denhoff [13d] stated that dermatologic patients possess a higher sensitivity rate than other patients.

THERAPEUTIC SHOCK

Therapeutic shock or Jarisch-Herxheimer reaction symptoms incident to the therapeutic use of penicillin in the treatment of syphilis are frequently encountered [32] and are considered evidence of the efficacy of penicillin.[33] Focal reactions are manifested by intensified chancre and other cutaneous lesions within eight to twelve hours or delayed for days in tissues of low vascularity, as in osseous syphilis. If treatment is started in the seropositive primary stage, before objective symptoms other than serologic are present, a profuse secondary rash may develop. Systemic reactions produce malaise, generalized aching, painful adenopathy, chill and elevation of temperature to 103 F. The symptoms usually subside within twenty-four to forty-eight hours, and treatment may be continued without interruption. If symptoms do not subside within a reasonable time, production factors other than therapeutic shock must be considered.

A Herxheimer reaction can be avoided by early reduced dosage of penicillin. It should be avoided in certain types of syphilitic infections, as in those of debilitated or toxic persons,[7b] particularly infants,[29d] and in late syphilis, gummatous, cardiovascular [34] and that of the central nervous system.[35]

Therapeutic shock symptoms occurring during the routine treatment of gonorrhea in which syphilis is not diagnosed or suspected or before the serologic reaction becomes indicative are considered diagnostic or at least suggestive of concurrent syphilitic infection.[36] Fever following the use of purified penicillin is rare and should arouse a suspicion of a Herxheimer reaction and syphilis.[37] Calloway and associates [38] did not consider that divided early dosage prevents fever. Therapeutic shock symptoms have followed the treatment of syphilis with oral administration of penicillin.[39] The incidence of Herxheimer reactions is high, 86 per cent [40] and 91.6 per cent having been reported.

Table 2.—*Toxic Reactions to Penicillin Produced by Contact (Epidermal) Sensitivity*

be considered. In late syphilis of the heart, too rapid healing of a coronary lesion by penicillin may produce deforming sclerosis and atresia so rapidly that no compensation can take place. This is a different process and independent of cardiac embarrassment following acute local vascular edema of the Herxheimer reaction. "Rapid healing with fibrosis in the liver results either in a diffuse contraction or localized deformities which affect the patient by obstructing his portal circulation, with resultant ascites, or by producing severe intractable jaundice."[41] Divided and cautious early therapy with penicillin will permit some degree of physiologic adjustment.

REACTIONS FOLLOWING INTRATHECAL ADMINISTRATION

Apparently penicillin has a direct irritating effect when applied to the central nervous system, and this property is contained in penicillin and crystalline penicillin rather than in the impurities. Walker and Johnson[42] showed that seven commercial penicillins administered intracisternally, intraventricularly and locally to the cerebral cortex produced convulsions and death due to vascular collapse in mice, cats, dogs and monkeys and that intracortical injections produced convulsive seizures in human beings. One hundred thousand units in 20 cc. of isotonic solution of sodium chloride produced cyanosis, irregular respirations and convulsions with temperatures to 104 F. and signs of vascular collapse in an infant.[43] Neymann, Heilbrunn and Youmans[44] stated that penicillin is toxic when it comes in direct contact with the surface of the brain, producing, as acute effects, headache, tenseness, muscular twitching, convulsions and cyanosis and, as chronic effects, meningeal irritation, rigidity of the neck and positive Kernig and Brudzinski signs. All symptoms were reduced after diminished dosage and particularly with concomitant use of barbiturate sedatives.[42c] Intrathecal reactions are apparently due to high dosage rather than to concentration of the drug and are not due to acidity or alkalinity of the solution, as sodium chloride and 95 per cent alcohol did not reproduce the symptoms.[45] The convulsive factor is related to the antibiotic properties of penicillin rather than to impurities, as convulsive seizures diminished directly proportionally to the destruction of the antibiotic properties by aging, boiling and acidifying and by dissolving penicillin in alcohol.[42a] There is a species factor in convulsive effects, as the threshold for monkeys is lower than that for cats.[42a] Crystalline penicillin produced the same reactions when used intrathecally.[42c] Five thousand units applied to the occipital cortex in human beings showed no clinical or electroencephalographic abnormalities, whereas 20,000 units produced encephalographic changes. Application of 10,000 units to the motor area resulted in twitching of the face and hands for three hours.[42a]

TABLE 4.—*Reactions Following Intrathecal Administration of Penicillin*

Listlessness
Headache
Nausea
Vomiting
Cold, clammy skin
Vascular collapse
Irregular respirations
Cyanosis
No blood pressure
Thready pulse
Muscular twitching
Clonic spasms
Flaccid extremities
Stiffness of neck
Convulsions
Comatose
Unconsciousness
Electroencephalogram changes
Spinal fluid cell count, globulin, albumin increased in nonsyphilitic patients
Positive Kernig sign
Positive Brudzinski sign

The convulsive effects of penicillin should not detract from its clinical intrathecal use when indicated, as the therapeutic dosage is usually below that which produces convulsions.[42c] A normal patient shows no reactions to doses from 3,000 to 5,000 units.[46] Patients have received from 20,000 to 100,000 units without reactions; however, the higher dosage should be used with caution.[47] Neymann, Heilbrunn and Youmans advised no dosage above 30,000 units.[44] It is noted that no reactions have been reported when penicillin is applied directly to wounds or abscesses in the central nervous system. This may be due to impaired diffusion of the drug through the walls of granulation tissue to adjoining nerve tissue.[42a]

From our present knowledge, reactions following administration of penicillin to the central nervous system are due to irritative, rather than allergic, therapeutic shock and paradoxic therapeutic reactions. Symptoms produced by these different types of reactions should not be confused.

CONCLUSIONS

1. Penicillin may produce reactions due to its action as (*a*) direct toxin and primary irritant, (*b*) antigen, (*c*) therapeutic shock excitant, and (*d*) indirect action on pathologic processes.

2. Salient observations concerning each action group are discussed.

3. Tables are presented listing toxic reactions encountered in each group.

1065 South 11th East.

ABSTRACT OF DISCUSSION

DR. HAROLD M. JOHNSON, Honolulu, Hawaii: It is gradually being realized that penicillin is not an innocuous drug. Two years ago, statements were made regarding the lack of toxicity and sensitizing effect. Now it is common to see new cases in which the reactions are mild to severe. In cases of the severe reaction, patients have stated that they would rather have their previous infection than penicillin therapy. The usual allergic reactions are mild and transient. Parenteral therapy has been continued in these cases. In the contact eczematous reactions, therapy was immediately discontinued. Usually the person can tolerate a fever, headache and bone-joint pain, but the itching and burning of epidermal sensitization require quick removal of the preparation. In 1944 a large drug firm stated, "The untoward reactions early attributed to penicillin unquestionably were in direct proportion to the toxic impurities rather than due to the penicillin." Recent reports appear to refute this

statement somewhat. Now patients allergic to one brand are allergic to the administration of penicillin from another manufacturer. Penicillin, a complex organic formula, could have increased its sensitizing ability by the manufacturer's change to newer commercial penicillin. It is possible, as Dr. Morginson stated, that persons may be sensitive to penicillin because they possess a varied sensitivity to all molds. This may well be the explosive factor seen in the exacerbation of a previous fungous infection. It is believed that a substantial percentage of the population is sensitive to crystalline penicillin sodium despite the fact that these persons have had no previous contact with this material. Theoretically this mold is ingested or inhaled, producing in susceptible persons a mild reaction with later changes in their immunologic responses. A few simple rules may help prevent reactions, such as the reduced dosage during the first six to twelve hours or even twenty-four hours, depending on the urgency in the case. The importance of the Herxheimer reaction to penicillin is proportional to the physiologic importance of the tissue involved. It is suggested that the patient be questioned regarding previous history of eczema, especially seborrheic, personal or familial, and history of cutaneous hypersensitiveness and chronic urticaria. Nine times out of ten these questions are never asked. Much grief by the patient and the physician could be avoided. Benadryl and Pyribenzamine (N'pyridil-N'benzyl-N-dimethylethylenediamine) can be used to alleviate the urticarial serum sickness-like reaction. If given early a great amount of discomfort can be eliminated. The dosage of Benadryl must be high in the severe reactions and frequently repeated. The drowsiness encountered can be fairly well controlled by oral administration of amphetamine sulfate. In a small series of cases I have been able to avoid the described reactions by the prophylactic administration of Benadryl, 100 mg. three times daily, during parenteral therapy and ten days following the ceasing of penicillin therapy.

Dr. Ben A. Newman, Los Angeles: The cutaneous reactions caused by penicillin are particularly important since penicillin is being more and more prescribed for comparatively minor infections (and even noninfections) of the skin and mucous membranes. The sequence of events that precipitated the innumerable sensitizations during the past decade of sulfonamide therapy is already being duplicated. Those who served with large military hospitals were impressed with the low incidence of reactions to penicillin. Its use in the armed forces was chiefly limited to the sulfonamide-resistant pneumonias, to the more serious surgical or medical infections and to the treatment of syphilis and gonorrhea. Generally the patients had never received penicillin previously, and the reaction rate did not exceed 2 or 3 per cent. This is in accord with the earlier reports on the use of penicillin On the other hand, in a group of patients I treated with penicillin for chronic infectious or eczematoid dermatoses the reaction rate exceeded 30 per cent. Although penicillin reactions from topical therapy in the acute infectious dermatoses have so far been minimal, I am willing to predict an increase in such reactions as more and more of the population are exposed to penicillin. Since my return to civilian practice, in addition to the many local contact dermatoses I have seen many instances of generalized urticarias, generalized erythemas and morbilliform rashes, vesicular eruptions and generalized eczematous eruptions from such use of the drug. Generally, these have occurred in patients who received penicillin in a previous instance. Experience among most dermatologists has shown that the use of penicillin externally in the form of an ointment or cream is of value only in the most superficial infections, that is, the impetiginous lesions. For deeper infections of skin or mucous membranes, topical applications are of limited value. The treatment of superficial impetiginous infections with topical application of penicillin does not appear to be superior to the therapies that have been used heretofore. Of even greater importance than cutaneous reactions from the topical use of penicillin is the probability that this usage of the drug will sensitize a large number of persons. Obviously, this is likely to prevent or complicate the administration of penicillin for serious systemic or organic infections. Penicillin is now available in the form of ointments, mouth washes, lozenges, lotions and first aid dressings as well as in the parenteral and oral forms. Its indiscriminate use for local infections of the skin and oral mucosa is to be condemned for the following reasons: first, the uncertain and questionable results over formerly established remedies; second, the potential hazard of sensitizing the patient to penicillin, and, third, the danger of precipitating untoward reaction in a previously sensitized patient.

Commander E. E. Barksdale, Bethesda, Md.: I entirely agree with the author and congratulate him on a worth while presentation. I should like to report some observations made by the Penicillin Control Committee at the Naval Medical Center during the past four years, during which time over 20,000 patients received penicillin for one condition or another. Craig and the other members of the committee reported the observations on the first 2,000 patients treated early in 1944; no reactions were reported other than those observed as mild Herxheimer reactions occurring in the treatment of early syphilis. Such is not the opinion of the committee at the present time. It is our opinion that the over-all reaction rate of penicillin is approximately 8 to 10 per cent. I should like to report also one death from exfoliative dermatitis. The case will be reported in the literature. The man was not a syphilitic patient but a patient with cellulitis who had been previously sensitized to penicillin while at sea. When admitted to this hospital with cellulitis, we knew that he was sensitive, but he was also sensitive to sulfonamide drugs. He was given 100 units of penicillin every three hours. At the end of the seventh dose, administration of it had to be discontinued because of a severe cutaneous eruption which went into a generalized exfoliative dermatitis, streptococcic septicemia and death. In addition to what the author has reported, we have observed several cases of neuritis and have frequently had complaints of pain in the peroneal nerve. We have had 5 cases of complete foot drop. I do not think that this is an allergic reaction; exactly what it is we are unable to explain. Fortunately, all 5 cases of foot drop did clear up on physical therapy, but 2 of them took five months to do so. When we first thought of using penicillin in the skin department of the Naval Hospital at Bethesda, about 80 to 90 per cent of the patients on the ward were getting local penicillin in one form or another, either ointment or wet dressings. At present there is not one patient on local penicillin. In my opinion, penicillin locally in any form is absolutely contraindicated. I agree with Flippen of Philadelphia in that I think that penicillin locally can sensitize a person so that he cannot take it intramuscularly or otherwise. I see no advantage of the local application over the intramuscular injections, either in oil or in aqueous solution.

Okinawans.—These examinations were made at a military government hospital from June 13 to July 30, 1945. Death was due to combat injuries in 100 cases, to noncombat (chiefly medical) causes in 36 and to a combination of war injuries and medical conditions in 14. . . . The most striking finding was the low incidence of retrogressive and degenerative changes. Senility came late, and cardiac and skeletal muscles remained well preserved even in the aged. Arteriosclerosis also developed late and to a moderate degree or not at all, and its lethal sequels in the brain, the kidneys and the heart were never seen. Hypertensive cardiovascular-renal disease was not seen except for 1 case of the type associated with toxemia of pregnancy. In fact, heart disease of all types, including congenital, rheumatic, bacterial endocarditic, syphilitic, hypertensive and coronary arteriosclerotic, was uncommon or absent. Renal diseases of all types were rare. Although cirrhosis of the liver was common, disease of the biliary tracts, including cholelithiasis, was not. After the life of these people had been studied, two possible etiologic factors appeared outstanding in explanation of these observations. They were (1) a low tension, placid, although physically strenuous, life and (2) a simple, predominantly vegetarian diet.—Steiner, P. E.: Necropsies on Okinawans, *Arch. Path.*, October 1946.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 854)

(NOTE.—*Following is the sixth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 6. 1849-1852

1849

BOSTON

In the amphitheater of the Massachusetts General Hospital in 1846 Dr. John Collins Warren had done the first public operation under ether anesthesia. At the meeting of the American Medical Association in 1849, held in Boston, he served as chairman of the committee of reception of the Massachusetts Medical Society; he was nominated President of the American Medical Association for the ensuing year. Whether or not there was any direct association between these facts there is, of course, no way to determine. The Association was still holding its sessions by a technic which involved the formation of special committees on such subjects as surgery, forensic medicine, indigenous botany and hygiene, but the primary interest was still the reform in medical education. The convention reiterated its approval of the resolutions on this subject adopted by the convention that met in Philadelphia in 1847. The attention of all the medical colleges was called again to the report on preliminary education. Already some agencies were endeavoring to find a substitute for clinical instruction in the hospital; a resolution was offered that the Association did not sanction or recognize college clinics as substitutes for hospital clinical instruction.

Significantly it was now agreed that state medical societies should be formed in every state in which they did not exist and that the societies should admit to their membership only those who had obtained degrees in medicine and had been licensed by a recognized licensing body.

Progress was made also in the resolution which encouraged all the schools of medicine to meet at Cincinnati before the next annual meeting of the American Medical Association and to present a plan for elevating the standard of medical education. These were the preliminary steps toward the high standard that was ultimately to prevail in the advancement of American medicine.

An innovation was the establishment of standing committees to undertake measurement of progress in each important medical field. To this resolution were appended the words "giving special attention to such as may be American." The committees included a Committee on Arrangements, Anatomy, Physiology, Materia Medica, Chemistry, Pathological Anatomy, the Principles and Practice of Medicine, of Surgery and of Obstetrics, Hygiene and Sanitary Measures, Forensic Medicine, Medical and Vital Statistics, American Medical Biography, Medical Education and Publication. These subjects of main interest were to be modified from time to time with the progress of medical science and with the advancement of knowledge in each of these specialties. Gradually anatomy, physiology, chemistry and pathology were to be directed for their scientific considerations primarily to special societies formed specifically for such purposes. Hygiene and sanitary measures, which were particularly the problem of the medical profession, were to be absorbed in the great field of public health administration. Medical and vital statistics became functions eventually of the Bureau of Census and the U. S. Public Health Service. American medical biography was to be merged gradually into the Directory of the American Medical Association. But in this formative stage each of these topics was considered of equal interest with every other; there was but one organization to give proper consideration to all of them.

Rather amusing in view of the present stage of medical education in the United States was the submission by the faculty of medicine of Harvard to the Committee on Medical Education of an elaborate defense of the limitation of the courses of medical instruction in the schools to four months—a limitation seriously opposed by the committee itself. A committee was appointed to prepare at leisure a statement of the facts and arguments which may be adduced in favor of prolonging the courses to six months.

Well in advance of their time also were resolutions indicating that the state medical associations in east Tennessee and New York had developed a series of popular lectures designed to enlighten the public mind in relation to the new position of medical men in relationship to society; it was urged that the American Medical Association recommend medical men in all associations, individually, by public lectures and otherwise, "to enlighten the public mind in regard to the duties and responsibilities of the medical profession and their just claims to the confidence of the public." Eighty years later the continuing demand for suitably informing the public caused the formation of a division of public relations in the American Medical Association.

Although but two years had passed, many members were beginning to get a little weary of the length of time required to read the annual reports. Their attention was called to the fact that the constitution merely required them to report on the progress of medicine in this country alone and only during the year of their service.

Realize too that, although the time was almost a hundred years ago, a resolution was offered requesting the Committee on Practical Medicine to inquire into the expediency of adopting the English language exclusively in the writing of prescriptions and in all directions for the composition and administration of medicines. This reform has still not reached the stage of majority approval.

These in the year 1849 were the chief interests of the American Medical Association from the point of view of its social, political and economic relationships. The reports of its special committees, however, merit at least a word because of some extraordinary interests. There was a report on the anatomy of the dodo, supposed by some to be a fictitious creation. It seemed, however, that the British *Forensic Medical and Chirurgical Review* of the previous year had published a report that this bird was not fictitious but that it was instead a massive and clumsy bird and that "we cannot form a better idea of it than by imagining a young duck or gosling enlarged to the dimensions of the swan." An investigator was convinced that there was no free hydrochloric acid in the gastric juice, and another insisted that there is nothing whatever to phrenology. Cholera was the major epidemic disease, and a gynecologist was treating dysmenorrhea by dilating the cervix of the uterus. A woman in Kentucky tried to poison her baby by giving it powdered glass, and another woman sued the doctor sixteen months after the baby was born because "he had placed hands upon her person." This action resulted from reading a book which was an attack on male obstetricians. There were extensive reports on the use of ether for anesthesia and a conclusion that all the accidents from anesthesia in the United States had resulted from the inhalation of chloroform. There had been 13 deaths from anesthesia by use of surgeons, 2 by dentists and 2 by people who had breathed chloroform for its pleasurable reactions. Typhoid raged rather widely, as did also an epidemic of streptococcic sore throat called angina, and several outbreaks of dysentery and intestinal disturbances. Cerebrospinal meningitis appeared in epidemics in a good many places, as did yellow fever.

The Committee on Surgery concerned itself also chiefly with anesthesia. Dr. J. Mason Warren had operated in a case of imperforate anus, but the progress of surgery was minute indeed. The Section on Obstetrics was chiefly concerned with misplacements of the uterus, but there was an extensive discussion on ovariotomy, which was spoken of as "this tremendous operation."

There are pages devoted to the right of the physician to use an anesthetic in labor. To this the committee wisely concluded that, "in the more severe obstetric operations, not only may anesthetics be rightfully given but they may not be rightfully withheld."

Extensive indeed was the report of the Committee on Medical Education, which offered a survey of medical education in the countries of Europe and a comparison of their education with the education offered in each of the medical schools of the United States. The continuous publication of such analyses of medical education has been one of the most potent factors in raising the standard of medical education in the United States.

The interest in public health caused the publication in the Transactions of that year of an analysis of the sanitary conditions in many of the most important cities and areas in our country. These pages constitute a source book for those interested in the progress of public health. The report from New Orleans is especially interesting in its attack on inebriety as a means of injury to the public health but more particularly in its endorsement of health education. In presenting the sanitary report of New Orleans, Dr. Edward H. Barton twice repeated the statement of Benjamin Rush that the medical profession was from twenty to thirty years ahead of the public in information in relation to health and that it required about that amount of time for the public to become sufficiently enlightened to realize the value of hygienic laws, observances and improvements.

Reports on drugs and indigenous botany occupied hundreds of pages which would be of little practical value to the physician of today with his specific synthetic chemotherapy.

One consideration for the Association was the question as to whether or not the introduction of water and gas into cities should be under the control of private agencies or municipal agencies.

As the convention came to its close, Dr. Thomas Wood presented a resolution requesting the Committee on Medical Science "to inquire into the expediency of establishing a board to analyze the quack remedies and endorsement now palmed upon the public and to publish the results of their examinations in a newspaper to be established for the purpose; and, further, to append such plain views and explanations thereto as will enlighten the public in regard to the nature and dangerous tendencies of such remedies."

1850

CINCINNATI

The year 1850 saw the convention moving as far west as Cincinnati, and an Ohio physician, Dr. Reuben D. Mussey, was chosen President.

The earlier resolutions on education had begun to bear fruit. A resolution of thanks was tendered to the faculties of the University of Pennsylvania and to the College of Physicians and Surgeons of New York and to all "other institutions which may have conformed to our recommendations." But medical education was still the most troublesome problem. One resolution demanded that young men be not admitted to medicine unless they had good moral character and had exhibited evidence of a good education. Daniel Drake amended this to demand "that the medical schools of the United States should require pupils to remain till the end of the session, whatever may be its length, except when permission may be given to depart," indicating that a good many boys who enrolled departed when the harvesting season or some other similar project demanded their presence elsewhere. Health education of the public was still a desirable object, and Dr. Austin Flint suggested that a popular address on some medical subject should be annually delivered at this Association before the citizens of the place in which the meeting is held. A few scientific papers were read, one the exhibition by Dr. Evans of Chicago, then professor of obstetrics in Rush Medical College, of a device which he called an obstetrical extractor, which he demonstrated on a manikin, and another by Nathan Smith Davis with the peculiar title "Has the Cerebellum Any Special Connection with the Sexual Propensity of Function of Generation?" This proved that there is nothing scientific about phrenology.

A resolution was passed condemning the clerical profession for "often—though, perhaps sometimes, unwarily—yielding their extensive influence in the community in giving currency to quackery and quack medicines."

Again in advance of public opinion and the times, another resolution proposed "that this Association regard it as contrary to its system of ethics for medical journals to advertise nostrums or secret remedies although their composition may have been made known to the editor."

The Association urged its support to the international copyright law. The Committee on Publications again recommended that the medical profession create its own medical literature rather than be subservient to that of England.

A group welcomed the action of the government which proposed to confer military rank on medical officers of the Army.

The meeting, being in Cincinnati, the Transactions are obviously a little less in scope and quantity than those of meetings held in the East nearer the great centers of population.

The Committee on Medical Literature called attention to the fact that a good many editors had already withdrawn to other departments of professional labor, some had tired of their ill paid toils and thankless duties, and some had been snatched away by the hand of death. For each of these losses the committee expressed its sense of bereavement. Already there were complaints that there were too many medical journals. The committee felt that the average value would be enhanced were the quantity reduced one half. Some of the medical journals, it seemed, had been established by gentlemen connected with medical schools and for the purpose mainly of sustaining the latter. Although the journals published at a distance from great medical centers were uniformly weak, the committee thought that they ought to be encouraged since their difficulties to exist were so great. The committee felt also that "it speaks but feebly in praise of our physicians as scientific investigators, that there are but two experimental memoirs of any importance contained in the journals of the last year." Incidentally one of these dealt with the actions of poisons and the other with the nervous system of the alligator.

Indeed the annual analysis of the medical literature of the day, which had come to be a regular feature at meetings of the American Medical Association, was significant in the gradual improvement in its quality. There is an essay on the functions of the critic or reviewer which might well be an inspiring text to any one essaying that thankless task in modern times. Analyzing the books that had been published in the previous year, the committee felt that the most extensive and important was the first volume of Dr. Daniel Drake's "Treatise on Diseases of the Interior Valley of North America." Incidentally, as an appendix to the report there is a complete bibliography of original articles of interest published in American journals between May 1849 and May 1850.

There follow the usual analyses of medical literature and of medical progress in a variety of fields, with a notable essay by J. Collins Warren on the use of anesthetics. This pointed out that already in his amphitheater in the Massachusetts General Hospital more than a thousand etherizations had been done without an unfortunate result. The introduction of anesthesia had permitted surgical operations not previously possible. J. Collins Warren reported also a number of operations for the removal of cancers and other tumors.

1851

CHARLESTON, S. C.

The fourth annual meeting convened in Charleston, S. C., in 1851. Dr. Alfred Stillé, who had served as secretary of the Association and who had written the memorable report on literature of the previous year, had been compelled to tender his resignation because his health had forced him to seek relaxation abroad.

Conspicuous among those who gave direction and impetus to the work of the American Medical Association during the formative years was Dr. Alfred Stillé of Philadelphia. Dr. Stillé was the son of Swedish emigrants, a graduate of Yale University in 1832 and of the University of Pennsylvania with an A.M. in 1835, the M.D. in 1836 and the LL.D. in 1839. Following his graduation in medicine he became house physician at Blockley under W. W. Gerhard. In association with Gerhard, he is credited with being among the first to make a clear distinction between typhoid fever and typhus. The great epidemic of typhus in Philadelphia in 1836 gave him opportunity for many postmortem examinations which permitted him to make a clear distinction between the two conditions and ultimately to convince the British physicians who had refused to accept such a distinction. In 1854 he became professor of the practice of medicine in the Pennsylvania Medical College, and in 1864 he succeeded the first Dr. Pepper in the chair of medicine at the University of Pennsylvania. He was the first secretary of the American Medical Association, and he was rewarded with the presidency in 1867.

Sir William Osler knew him well, but only after Stillé had passed his seventieth year. Of him Osler wrote "He had none of those irritating features of the old doctor, who, having crawled out of the stream about his fortieth year, sits on the bank, croaking of misfortunes to come, and, with less truth than tongue, lamenting the days that have gone and the men of the past." In his valedictory address Stillé said "Only two things are essential; to live uprightly and to be wisely industrious."

The representative session was largely concerned with whether or not to admit delegates from dentistry and pharmacy into the convention, with an attempt by the Congress to repeal the law that it had passed conferring military rank on military physicians, and with continuing emphasis on the improvement of medical education.

A variety of special committees were suggested to investigate special diseases as well as epidemics. Another committee was established to receive volunteer communications and to offer a prize for the most meritorious. This year the versatile Dr. Davis read a paper on an experimental inquiry concerning the processes of assimilation and nutrition.

For those interested in budgets, the annual expenditures of the Association amounted to $1,100. Since there was a slight surplus in the treasury, some of it was made available for publishing. The prizes for the most meritorious essays came from fifty dollar gifts made by Dr. Alfred Stillé and Dr. F. G. Smith.

1852

RICHMOND, VA.

Richmond got the meeting for 1852, and in due course a Virginia physician, Dr. Beverley R. Wellford, became President. The society adopted a resolution admitting a delegate from the American Medical Society of Paris.

Dr. Austin Flint of Buffalo won the prize for the most meritorious essay out of sixteen voluntary communications. The subject of his essay was "On Variations of Pitch in Percussion and Respiratory Sounds, and Their Application to Physical Diagnosis." The essay received, incidentally, the unanimous vote of the committee.

This year the scandal in transportation of steerage passengers from Europe to the United States attracted the attention of the Association. The following resolution was introduced:

> The accumulation of passengers who are emigrants, crowded in ships coming to our shores from foreign ports, having in a great many instances numerous cases of aggravated fever, many of which prove fatal, and likewise producing similar results at the lazarettos, and even cities; the number, likewise, of sick arriving from California, and some of the South American ports, and the fact that none of these vessels are required by law to have physicians or surgeons on board, seem deserving of our attention as conservators of health, and as an act of humanity and duty on the part of the American Medical Association, to bring these facts respectfully to the consideration of Congress, and to request its legislation thereon; Be it therefore
>
> *Resolved,* That the American Medical Association do memorialize Congress to require all vessels carrying steerage passengers on the sea to have a surgeon on board.
>
> *Resolved,* Further, that a committee of this Association be appointed to draw up a memorial to Congress, making such suggestions as it may deem fit as regards the importance of this measure.

Now there arose also some complaint of doctors not connected with the faculties of the medical schools against the monopolization of practice by the teachers. A resolution was offered suggesting that "it be considered unethical to operate upon the legitimate patient of any other physician, knowing that to be such and that the possible perversion of clinics to the private emolument of those conducting them should be scrupulously guarded against."

A committee was set up to declare the contents of a medicine chest for a merchant ship and the directions that ought to go along with it.

There were new attacks on the quality of medical education and defenses by those who were for the status quo. There were amendments to the constitution and by-laws, with an interesting suggestion that the University of Virginia should be entitled to representation in the Association, notwithstanding the fact that it did not have six professors and that it did not require three years of study.

Some twenty-seven essays had been offered to the committees that were to award the prizes. There came a resolution that one prize of $250 be awarded instead of five prizes of $50 each, but another amendment that there be two prizes of $100 each prevailed.

A good many papers were read by title and offered to the publication committee.

Incidentally the resolution giving special courtesy to the University of Virginia prevailed "but only so long as the present peculiar system of instruction and examination practiced by that institution shall continue in force."

This year the income of the Association doubled but so did its expenditures, so that there was left in the treasury the sum of $56.75.

What had been going on elsewhere in the world that should perhaps have attracted more attention at the assemblages of the American Medical Association than seems to have been given?

In France, Claude Bernard was making fundamental discoveries year after year. In 1848 he had discovered the glycogenic function of the liver. In 1849 he had produced diabetes by puncture of the fourth ventricle, and in 1851 he had explained vasomotor functions of the sympathetic nerves.

In 1844 Addison had described pernicious anemia and adrenal disease. Helmholtz had measured the velocity of the nerve current, and several surgeons had operated to relieve abscess of the brain. The hypodermic syringe was invented in 1852 by Pravaz, and little was it realized how frequent would be its use at the end of one hundred years. In 1853 the Crimean war apparently stirred little interest in the meetings of the American Medical Association, but that was the war in which Florence Nightingale founded the profession of nursing. Today questions of nursing are at the very forefront of all considerations in the field of medical care.

The year 1855 saw the introduction of the laryngoscope by Manual Garcia. The Bunsen burner was invented. J. Marion Sims founded a hospital for women's diseases in New York City. Perkins developed the aniline dyes as coal tar products in 1856; from this first step came such remedies as the salicylates, aspirin and eventually arsphenamine and the sulfonamides. Then in 1857 Graefe introduced his operation for strabismus; Bouchut performed intubation of the larynx.

The operation described by J. Marion Sims in 1852 was the result of a number of discoveries beginning in 1845 which involved the development of the peculiar lateral posture known as the Sims position, the invention of the special curved speculum, the use of silver wire for sutures and of the catheter for emptying the bladder while operating on the uterus. The monumental paper of Sims was published in 1852 in the *American Journal of the Medical Sciences* in Philadelphia. It created a profound impression throughout the world. In 1853 he moved to New York, where he founded the hospital for women, which soon became the center of the best gynecologic work of its time. Such procedures were already beginning to add fame to the progress of medicine in America.

Perhaps the most significant book in these first ten years following the founding of the American Medical Association was Daniel Drake's work on "Diseases of the Interior Valley of North America." As pointed out by Fielding Garrison, this was the result of thirty years of labor based largely on personal observation. The first volume is an encyclopedia of the geography, topography, climate, plants and animals and population of the Mississippi Valley; the second volume, an account of malaria and other fevers and of the various epidemics in their relation to the geography, meteorology and topography of the area concerned. This was the first work of its kind since the treatise of Hippocrates on "Airs, Waters and Places" but went even beyond Hippocrates on its relation of epidemiology to geography. When Alfred Stillé reported on it at the meeting of the American Medical Association in 1850, Drake was greeted with prolonged and thunderous demonstrations of applause and enthusiasm such as had been seldom accorded to any American physician previously. Dr. John Shaw Billings reports that "he covered his face with his hands and wept like a child." Daniel Drake, as described by S. D. Gross, was a tall, commanding figure, simple and dignified in manner. "He was always well dressed, and around his neck he had a long gold watch-chain, which rested loosely upon his vest." He lectured with a splendid voice and with fiery eloquence.

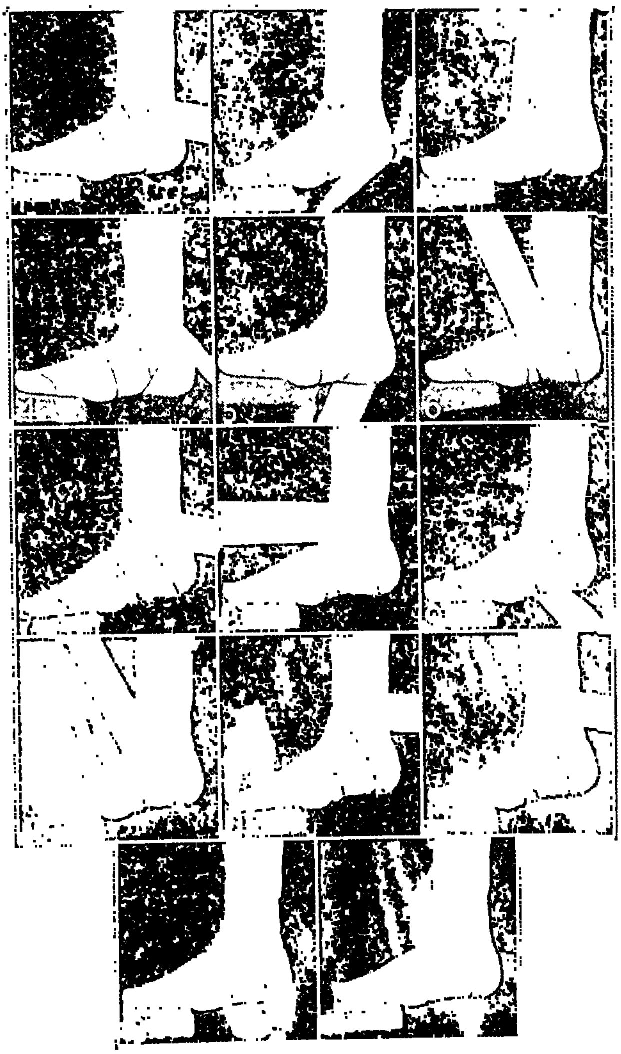
Clinical Notes, Suggestions and New Instruments

A PROTECTIVE WRAPPING FOR THE ANKLE

T. B. QUIGLEY, M.D.
JAMES COX
and
JOSEPH MURPHY
Boston

The vulnerability of the ankle has long been known to athletes and trainers, and protective bandaging is commonly practiced. The usual wrapping consists of turns taken in a "figure 8" fashion around the malleoli and foot, crossing at the anterior aspect of the astragalus. When critically examined, this bandage really accomplishes little; neither lateral nor anteroposterior motion is greatly limited, and little protection is afforded against sprain or fracture



Steps (1 to 14) in application of protective ankle wrapping.

For the past fifteen years at Harvard College every student who participates in contact sport has been taught a method of wrapping the ankle which considerably limits lateral motion without interfering appreciably with flexion or extension. During this period, not one player wearing this wrapping has suffered a complete rupture of an ankle ligament. When sprains do occur they are minor, and the average period of disability, before return to full athletic participation, has been only eight days.

A considerable number of former college athletes, having learned to apply the wrapping as undergraduates, have used it enthusiastically on weekend skiing expeditions. With the growing popularity of winter sports and the high incidence of injuries to the ankle among amateur skiers and skaters, a description of the method seemed worthy of publication.

Bandages are cut to 100 inch (254 cm.) lengths from 2¼ inch (5.7 cm.) nonelastic ribless muslin tape and thoroughly shrunk by washing in extremely hot water before use. The wrapping is applied over the inner of two pairs of smoothly fitting socks. The toes are placed on the edge of a chair, and the ankle is held firmly at an angle of 90 degrees. The end of the bandage is placed at the lateral malleolus and unrolled snugly, without wrinkles, over the proximal end of the first metatarsal, across the sole, upward, crossed at the center of the ankle joint and back over the medial malleolus (1 in the illustration).

At this point it is angled sharply downward across the lateral aspect of the os calcis, carried across the sole, upward on the medial aspect of the foot and over the lateral malleolus (2, 3 and 4). Again it is angled sharply downward, this time over the medial aspect of the os calcis, carried across the heel and up around the medial malleolus (5, 6 and 7). The remaining turns are of the "figure 8" type around the tarsus and ankle at and just above the malleoli (8 to 14 inclusive). A "figure 8" turn of 1 inch (2.5 cm.) adhesive tape anchors the final turns.

SUMMARY

A protective wrapping for the ankle, for use by college athletes and others, is described. It can be applied by the athlete himself and reduces the incidence and severity of sprains of the ankle by limiting lateral mobility at the ankle joint without interference with flexion and extension.

MASSIVE HEMATURIA DUE TO DICUMAROL OVERDOSAGE

DAVID ROSENBLOOM, M.D., and JAY J. CRANE, M.D.
Los Angeles

Dicumarol (3, 3′-methylene-bis-[4-hydroxycoumarin]) is the active principle in spoiled sweet-clover hay which causes hemorrhagic disease in cattle, and it is now made synthetically.[1] Physiologically, it suppresses thrombin formation[2] and impairs clot retraction,[3] and should be administered only if daily determinations of prothrombin time are made.[2] The usual dosage is given as 200 to 300 mg. initially, followed by 100 to 200 mg. a day orally. A twenty-four to forty-eight hour lag (sometimes five days[4]) is followed by an increase in the prothrombin time, and the normal time of 12 to 14 seconds[5] should not be permitted to increase beyond 35 to 60 seconds.[3] Daily prothrombin times should be taken, and preferably the patient should be hospitalized. After withdrawal of the drug, complete recovery takes six to ten days.[4] Overdosage is usually followed by bleeding from various sites of the body. Cohan[6] reported purpura after 2,800 mg. in thirty-two days had been given for postoperative emboli; hematuria persisted eight days after the withdrawal of Dicumarol, and a prolonged bleeding time with definite prothrombin deficiency was present, but platelet reduction or clot retraction abnormality was not observed.

Zucker,[7] in 18 cases in which an initial dose of 300 mg. of the drug was followed by daily doses of 200 mg. observed in 1 patient on the fourth day, a petechial rash of the upper extremity with a concomitant microscopic hematuria of 30 erythrocytes; 4 other patients had microscopic hematuria. Pfeiffer and Sain[2] have observed microscopic hematuria. Lucia and Aggeler[4] reported hematuria on the tenth day of Dicumarol administration (for thrombophlebitis) persisting to the seventeenth day, accompanied by epistaxis, ecchymoses at the sites of hypodermic injections and at herpetic lesions on the lip. Inquiries of several urologists in this city have elicited at least 2 instances of gross hematuria, both of which were definitely attributable to the ingestion of Dicumarol for thrombophlebitis.

Treatment of hematuria caused by Dicumarol consists of discontinuance of the drug, the administration of multiple blood transfusions,[8] and the administration of vitamin K_1 oxide[9] in large amounts (500 or more milligrams). Ordinary synthetic vitamin K is considered to be of little value,[10] although Smith and Kaufman[11] have employed it.

REPORT OF CASE

S. D., a man aged 32, was seen in consultation on Sept. 7, 1945. He stated that when he arose on the morning of Sept. 2, 1945 he had found fresh blood, which had apparently come from his gums, on the pillow; later in the day he had observed gross massive hematuria, so that the urine looked like "pure blood." His physician had made a diagnosis of "nephritis" and had put him to bed on a milk diet. Because of diffuse abdominal pain, an additional diagnosis of "ulcer" was made. One day before the onset of the hematuria, varicose veins in each leg had been injected with sodium morrhuate.

When we saw the patient, the urine was deeply bloody. Careful physical examination failed to demonstrate any abnormalities other than diffuse abdominal guarding and tenderness, and pronounced tenderness of the lumbar and renal area. Masses were not palpable, and normal peristaltic sounds were heard. Slight bleeding of the gingival margin also was present. He was hospitalized on Sept. 8, 1945, and hematologic studies demonstrated a bleeding time of 14 minutes, clotting time of 7½ minutes and a prothrombin time of 112 seconds. Examination of the blood revealed that erythrocytic, leukocytic, thrombocytic, and differential counts were within normal limits. An abdominal roentgenogram did not show calculi or other abnormalities of the urinary tract. The nonprotein nitrogen was 26 mg. per hundred cubic centimeters. At this time the patient was thoroughly requestioned and the history was elicited that in the seven days preceding Sept. 1, 1945, the day of the varicose vein injections, he had taken 46 capsules; the dispensing pharmacist was consulted and stated that the capsules each contained 50 mg. of Dicumarol. Therefore, 2,300 mg. of Dicumarol had been ingested within seven days.

The patient was immediately placed on a regimen of 40 mg. of synthetic vitamin K every two hours for six doses, followed by similar doses every six hours, and vitamin C, 250 mg., every six hours. Vitamin K_1 oxide was not obtainable. Strict rest in bed was enforced. However, the gross hematuria and abdominal pain did not diminish. A transfusion of 500 cc. of citrated blood was administered on September 10, and the procedure was repeated on September 11; on September 12 the hematuria began to lessen. On this day, the patient suffered six severe bilateral renal colics, requiring multiple injections of morphine for relief. These were interpreted as the passage of blood clots down each ureter. On September 13 the temperature suddenly rose to 102 F., and the fever was attributed to a transfusion reaction, postcolic mild pyelonephritis or ureteral trauma. He was given penicillin, 20,000 units every three hours, and sulfadiazine and sodium bicarbonate, 1 Gm. of each, four times a day. The fever promptly subsided, and by September 14 the urine was grossly clear. The patient was dismissed on September 15, afebrile and with clear urine. He was seen on September 16; he felt "washed out" but otherwise normal, and a voided specimen contained only an occasional erythrocyte when viewed microscopically. On September 22, a complete hematologic study was within normal limits. The prothrombin time was 14 seconds. An excretory urogram showed a normal urinary tract.

SUMMARY

A 32 year old man received 2,300 mg. of Dicumarol in seven days (approximately three and a half times the normal dose). Two days later, massive hematuria appeared. Synthetic vitamin K therapy was ineffective. Cessation of bleeding followed the transfusion of 1,000 cc. of blood.

COMMENT

In the differential diagnosis of hematuria, Dicumarol (3, 3'-methylene-bis-[4-hydroxycoumarin]) administration should be considered. *The patient should be questioned about recently* ingested drugs.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

OTARION MODEL A-4 JR. HEARING AID (SINGLE PACK) ACCEPTABLE

Manufacturer: Otarion Hearing Aid Company, 448 North Wells Street, Chicago.

This single pack hearing aid is a three tube instrument with transmitter and batteries in a pigskin leather case. A four position tone control lever is at the top of the case, and the combined on-off switch and volume control are on the side of the case. A magnetic type receiver is supplied with this instrument. The Otarion Model A-4 Jr. Hearing Aid is convertible, since it may be worn as a single pack (with transmitter and batteries in a single case) or with a separate battery case or pack in the conventional manner.

Dimensions: The case measures 1 by $2\frac{9}{16}$ by 5¾ inches (2.54 by 6.60 by 14.6 cm.).

Weight: The case (containing batteries and transmitter), receiver and cord weigh 9 ounces (255 Gm.).

Current consumption: A battery (1½ volts), 65.0 milliamperes, B battery (30 volts), 0.6 milliampere.

Maximum Acoustical Gain

Frequency	250	500	1000	2000	3000	4000	5000 cycles/second
Tone control							
White	27.5	33.5	39.0	42.5	34.5	26.5	14.0 decibels
Black	26.5	33.5	42.5	50.0	45.0	38.5	26.0 decibels
Green	21.0	28.5	39.0	47.5	43.5	37.0	25.0 decibels
Red	14.0	23.5	34.0	43.5	40.0	34.0	23.0 decibels

With the tone control at the white dot position the high frequencies are attenuated. In the black position the instrument reproduced with maximum width of frequency range. In the green position the low frequencies are moderately attenuated, and in the red position the high frequencies are attenuated maximally.

Performance: The instrument operates in an entirely satisfactory manner. There is a minimum of inherent noise. The pigskin leather case produces a slight amount of frictional noise, which is not perceptible when the transmitter is worn as a separate unit with a separate battery case.

The Council on Physical Medicine voted to include the Otarion Model A-4 Jr. Hearing Aid (Single Pack) in its list of accepted devices.

STREPTOMYCIN IN INFLUENZAL MENINGITIS

The mortality rate in Hemophilus influenzae meningitis was until recently above 92 per cent. Following the introduction by Alexander[1] of rabbit serum containing antibody against type B organisms, which she employed in combination with sulfadiazine, a reduction in the mortality rate to 26 per cent in a group of patients ranging in age from 3 months to over 5 years was reported.[2] In experiments on mice, Alexander and Leidy[3] demonstrated that streptomycin alone was more effective against massive H. influenzae infections in mice than serum used in conjunction with sulfadiazine. The results of treating 25 patients[4] who had H. influenzae meningitis of type B with streptomycin alone or in conjunction with serum and with serum and sulfadiazine suggest that streptomycin alone will bring about complete recovery when the infection is of mild or average severity. In 9 of the 12 patients who recovered on streptomycin therapy the spinal fluid cultures proved sterile twenty-four hours after initiation of streptomycin therapy, in the other 3 after forty-eight hours. The return to normal of the chemical constituents of the spinal fluid was equally rapid. Now Alexander recommends administering all three agents initially: streptomycin, type specific antiserum and sulfadiazine.

Logan and Herrell[5] employed streptomycin, sulfonamides and antiserum in the treatment of 4 infants suffering from H. influenzae meningitis. In 2 of these clinical and laboratory evidence of improvement did not occur until streptomycin was used. Three patients recovered. In the fourth, H. influenzae was eliminated from the cerebrospinal fluid after treatment with streptomycin, but the patient died several weeks later as a result of hydrocephalus. Weinstein[6] reported recovery in 8 out of 10 cases of purulent meningitis caused by H. influenzae of type B in 8 and by an untypable strain in 2. Streptomycin was given intramuscularly in doses ranging from 15,000 to 125,000 units every three hours and intrathecally in amounts varying from 10,000 to 25,000 units every twenty-four hours. Two of the 9 patients with influenzal meningitis treated with streptomycin died. One showed complete absence of response to the antibiotic agent. The other died of an intercurrent Staphylococcus aureus bronchopneumonia which was not affected by penicillin. The blood and spinal fluid were cleared of the causative organism in twenty-four to forty-eight hours in all cases except the 2 due to atypical strains. Relapses or sequelae were not observed in any of the recovered patients in six to ten weeks after the cessation of streptomycin treatment.

Of the 8 patients with H. influenzae meningitis treated by Birmingham and his associates[7] 4 recovered, 3 died and in 1 streptomycin therapy was given up in favor of sulfonamide and serum. Death in 1 case was associated with the appearance of drug fastness. Toxic reactions included erythema, urticaria, increase in meningeal signs, persistence of pleocytosis, local pain on injection and mild shock on initial administration. None of these were serious. Nussbaum and his associates[8] treated 3 children less than 2 years old with streptomycin intramuscularly and intrathecally and sulfadiazine, with recovery without complications or sequelae.

Further lowering of the mortality rate and lessened incidence of complications and sequelae may be accomplished by early diagnosis and initial employment of the three therapeutic measures streptomycin, the antibody rabbit serum and sulfadiazine. In any event the physician is no longer confronted with a hopeless prognosis in this meningeal infection.

MYTH AND MUMPSIMUS IN MEDICINE

"Myth and Mumpsimus," by Forbes,[1] concerns iconoclastic attitudes toward accepted beliefs and dogmas. Although medicine is not an exception, myth and mumpsimus have a way of lingering because of mental inertia and faith in traditional custom. "Mumpsimus" stands for "a traditional custom, obstinately adhered to however unreasonable it may be." It is a corruption of sumpsimus, first person plural indicative perfect of the Latin verb *sumo,* I take. With regard, for example, to the traditional forcing of fluids on patients with or without pyrexia in the hope of "aiding in the elimination of toxins," what is objected to is not the rationale of the procedure of replacing the loss of body fluids in a sweating febrile patient but the conception of the body as some sort of "involved water-closet to be cleansed by flushing with copious drafts of imperial drink." The ritual purgation in acute food poisoning and administration of magnesium sulfate in infective hepatitis "to promote the free flow of bile" are evidently based on misconceptions of the pathogenesis of these disorders.

[8] Nussbaum, Sydney; Goodman, Solomon; Robinson, Clarence, and Ray, Louis: Influenzal Meningitis, J. Pediat. **29**: 14 (July) 1946.

[1] Forbes, J. R.: Myth and Mumpsimus, Lancet **2**: 293 (Aug. 31) 1946.

Forbes is probably correct in stating that we do not have reason to think that diet is of any real importance in those diseases which are not associated with gastrointestinal dysfunction or with a definite upset of metabolism. He believes that the enforced disappearance, due to rationing and food shortage in England, of dietary regimens in the last few years has not led to any appreciable increase in death or disease. He thinks rather that many patients are the better for it. His peptic ulcer patients did not relapse any more frequently since he ceased to recommend a carefully selected diet for six months or longer, and he now merely advises them to eat within reason whatever food they find does not disagree. His patients seem to be better because they no longer feel obliged to consider their stomach before all else and to debate the digestibility of each dish before them. Physiologists will probably agree that appetite, when not perverted by gluttony or hysterical inhibitions or falsely determined by injudicious medical advice, is a reliable guide to what is and what is not good for a sick person. The forced overeating of patients with normal appetites, as was formerly practiced on consumptive persons, is in his opinion as foolish as undereating. The custom is disappearing, but its place threatens to be filled by the habit of indiscriminate prescription of vitamins. The medical profession in the United States will subscribe to the statement that the mythical healing properties attributed to vitamins by now far exceed their very real ones.

Prolonged immobilization of older patients, contributing as it does to the dangers of venous thrombosis and passive pulmonary congestion, is being discarded in favor of early ambulation. The same tendency to limit prolonged absolute rest is evident in the treatment of coronary thrombosis. The psychic damage to the person caused by the indiscriminate use of either correct or erroneous medical terms is not sufficiently appreciated by the profession. Forbes questions whether it is wise to inform our symptomless hypertensive patients of the state of their blood pressure. A young man with a functional systolic murmur, who gives a history of ten days of "rheumatism" in childhood, whose mother died of some vague "heart trouble" and who shows an inverted T wave in the third lead of his electrocardiogram, is almost certain to be diagnosed some time as having rheumatic heart disease, though he probably is normal and healthy. Such a diagnosis may have a devastating effect on a suggestible youth, leading to a cardiac neurosis which may result in a life of useless semi-invalidism. The author believes that such an error is at least as great as that of failing to detect a carcinoma in a man of 60. The number of outworn beliefs and practices is naturally multiplied in the field of drugs.

An iconoclastic attitude which insists on experimental and clinical demonstration of the validity of any practice is the surest antidote against myth and mumpsimus.

METHEMOGLOBINEMIA AND TISSUE OXYGENATION

Methemoglobin is a derivative of a normal respiratory pigment, produced by the action of various compounds among which are chlorates, nitrites, acetanilid, nitrobenzene, sulfonal and sulfanilamide. Whereas the oxygenation of hemoglobin produces a derivative (oxyhemoglobin) from which oxygen is readily eliminated under the conditions existing in the tissues, methemoglobin is relatively stable in the body and does not release its contained oxygen for purposes of tissue respiration. As the proportion of methemoglobin increases in the circulation, hypoxia develops and cyanosis appears. The increased incidence of methemoglobinemia following the use of sulfonamide drugs and the suggested therapeutic use of methemoglobin in the treatment of cyanide poisoning raise the question as to how far the favorable action of this derivative can be evoked without interfering with tissue oxygenation.

A recent report[1] describes experiments on human subjects. Relatively untrained as well as trained young men worked on a bicycle ergometer. The initial increase in concentration of lactic acid in the blood together with the subsequent removal was used as an objective index of oxygenation of the muscle. Comparison of the data secured in control periods with those obtained after part of the circulating hemoglobin had been changed to methemoglobin (oral administration of p-aminopropiophenone[2]) permitted conclusions regarding the effect of the altered respiratory pigment on tissue oxygenation. When 8 to 17 per cent of the blood pigment had been changed to methemoglobin, little if any effect on the rate of removal of lactic acid after exercise was noted in relatively untrained men. However, when the proportion of the oxidized pigment was increased to 22 per cent, there was definite evidence for the interference with muscle oxygenation after measured light exercise. Training for the mechanical work seemed to minimize the deleterious influence of methemoglobin on the oxygenation of muscle. However, when the severity of the work was increased the trained subjects, gave indication of impaired oxidative removal of lactic acid from the blood.

The evidence cited points to definite limits of concentration of methemoglobin in the circulating blood beyond which there is interference with tissue oxygenation. Analytical methods for the quantitative estimation of this pigment are available, and information based on their use should be a reliable guide to management of patients in situations which promise to be somewhat more common.

Current Comment

POSTGRADUATE COURSES FOR PHYSICIANS

Semiannually the Council on Medical Education and Hospitals of the American Medical Association publishes lists of postgraduate courses offered to physicians throughout the country for the ensuing six months. In this issue of The Journal the course listings cover the period from Jan. 1, 1947 to July 15, 1947. With the increasing demand for such work from physician veterans there has been a continued increase in the number and variety of offerings. In the current listing there are approximately eight hundred courses offered by about ninety institutions and organizations, which is by far the largest number yet published for any six month period. The medical schools take a prominent part in presenting these courses. Forty-three schools will participate in the presentation of over five hundred courses. In addition a number of the courses, while not given by a medical school, will employ the facilities of medical schools. The wide usefulness of these listings is evidenced by the tremendous demand for reprints. Institutions and individuals participating in these programs are rendering a great service to the profession and to the physician veterans. The Journal and the Council are indebted to them for making publication of the lists possible.

RECENT ADVANCES IN HUMAN GENETICS

Penrose[1] recently analyzed the familial data in 144 cases of anencephaly, spina bifida and congenital hydrocephaly. The data comprised 137 sibships, which were selected on the basis of at least one child affected with the three congenital conditions mentioned. In seven of these sibships a second case of one or other of the conditions occurred. Statistical calculations were made which showed that advancing maternal age bore a significant relationship to the incidence of this group of malformations. When maternal age was eliminated as a factor by statistical means, primogeniture was shown to have some probable etiologic significance. The first of these tentative conclusions conforms with opinions expressed by Murphy[2] and others in this country. In the same issue of the *Annals of Eugenics* Harris[3] has presented what amounts to a scientific study of the commonly made statement that some families run principally to boys or principally to girls. His report is based on a family of watchmakers in England whose family tree could be accurately traced since 1690. During this period thirty-five children were born into the family, of which only two were girls. Harris said that there is small probability of such a sex ratio occurring by chance and that therefore the hypothesis that some hereditary tendency is at work would appear reasonable. An examination of the seminal fluid was made on one representative of this family. In number, percentage, motility and percentage of abnormal forms the spermatozoa were within the usual normal limits. Definite microspermatozoa, that is, smallness in size of the sperm heads, was found. Consequently Harris suggests that there may be a genetic interconnection between individual relative sexual inactivity (as in the case of the man in question), spermatozoa of unusually small head lengths and a family showing a tendency to infertility and the propagation of predominantly male progeny.

THROMBOSIS AND EMBOLISM IN SWEDEN

Zilliacus[1] has recently summarized the results of treatment in 1,158 cases of deep venous thrombosis and pulmonary embolism in twenty Swedish clinics from 1940 to 1945. Comparisons were made of conservative treatment, heparin therapy and Dicumarol (3-3′-methylene-bis-[4-hydroxycoumarin]) therapy. Deep venous thrombosis or sudden pulmonary embolism occurred in 646 (0.51 per cent) of 125,524 surgical patients, 387 (0.40 per cent) of 96,672 obstetric and gynecologic patients and 125 (0.37 per cent) of 34,086 medical patients. Pulmonary embolism developed in 44 per cent of the surgical and 22 per cent of the obstetric patients with deep venous thrombosis. Calculated on the total number of patients admitted, the incidence of pulmonary embolism was 0.23 per cent, with mortality rates of 0.105 per cent in surgical cases, 0.011 per cent for obstetric and gynecologic cases and 0.053 per cent for medical cases. Of 214 cases of deep venous thrombosis of the leg treated conservatively, the thrombosis spread to the thigh in 4 out of 5. In contrast, it was confined to the lower part of the leg in approximately half of 576 patients given specific anticoagulant therapy. Of patients who received the best attention as to early diagnosis and treatment, the thrombosing process was confined to the calf in 4 out of 5. In 30 per cent of the conservatively treated group the thrombosis spread to the other leg, whereas this occurred in only 1.4 per cent of those in whom specific therapy was applied. A striking absence of late sequelae was noted in those patients in whom the acute thrombotic process was restricted to the lower part of the leg. Of 282 cases of sudden pulmonary embolism death occurred in 114 within such a short time that opportunity was not afforded for specific treatment. However, in contrast to 21 deaths among 65 patients treated conservatively, there was no mortality in a group of 103 patients who received anticoagulants (71 with heparin, 16 with heparin and Dicumarol and 16 with Dicumarol alone).

ORGANIZATION SECTION

Official Notes

THE ATLANTIC CITY SESSION

Applications for Space in the Scientific Exhibit to Close January 13

The Committee on Scientific Exhibit of the Board of Trustees has authorized four special exhibits for the Atlantic City session: Fractures, Physical Medicine, Heart Disease and Fresh Pathologic Material. Each exhibit will be presented by a special committee assisted by a large group of demonstrators.

In addition to the special exhibits, each section of the Scientific Assembly will present groups of exhibits dealing with the various specialties of medicine. Applications for space in these section exhibits are now being received and will close on January 13. Application blanks may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

Washington Letter

(From a Special Correspondent)

Dec. 9, 1946.

Top Scientists Sought for Federal Service

Arthur S. Flemming of the U. S. Civil Service Commission informed the annual meeting of the Association of Science Teachers that the government plans to increase its cooperation with colleges and universities to develop scientists and other professional men for positions in the federal service. He said it was essential that government laboratories be staffed with scientists who were "second to none," and he advocated raising the federal pay ceiling from $10,000 to $15,000 annually to attract and retain persons of the highest caliber.

Socialized Medicine Criticized

John H. Hayes, president of the American Hospital Association, told the Maryland-District of Columbia Hospital Association that socialized medicine was an experiment which would cost more in taxes and salary deductions than present hospital care. He stated that if the present charitable work of physicians, community chest agencies and others were matched by a government subsidy, the amount would "stagger even a Congressman." Socialized medicine, he said, would result in poorer medical care, increased public debt and heavier salary deductions.

New Facilities Aid Research on Common Cold

Dr. R. E. Dyer, director of the National Institute of Health at Bethesda, Md., announced that new facilities will be put to work in a study of the common cold, part of a broad gage research program to see what science can do to prevent and cure this common malady. Colds keep an average of 250,000 people absent from their work daily, according to a U. S. Public Health Service survey. This research is part of the comprehensive attack by the institute on the principal diseases afflicting human beings.

The C. I. O. Will Seek More Health and Welfare Features in Contracts

Following the report by THE JOURNAL that the American Medical Association approved "cooperative health planning by management, labor and medicine, provided scientific and ethical standards are maintained," the C. I. O. announced that it planned to endeavor to incorporate more health and welfare features in union contracts. An extremely favorable stand toward the editorial position of THE JOURNAL was noted in several governmental sources.

International Exchange of Students as Step to World Peace

Professor Robert Andrew Milliken, Nobel prize winner of the California Institute of Technology, declared that the most hopeful prospect for world peace is to stimulate the exchange of teachers and research workers between countries. He was one of several noted speakers attending a convocation and reception at the National Museum commemorating the hundredth anniversary of the Smithsonian Institution. Also present were delegates from the National Academy of Sciences, the American Philosophical Society and various foreign scientific organizations, including the British Royal Society and the Institute de France. Dr. L. P. Eisenhart, executive director of the American Philosphical Society, and Dr. Frank B. Jewett, president of the National Academy, brought greetings to the institution. Dr. Vannevar Bush, president of the Carnegie Institution of Washington, presided as representative of the Smithsonian board of regents.

Millionth Baby Born with Birth Expenses Paid by Government

The Federal Security Agency announced that during the past week the millionth baby was born somewhere in the United States whose birth expenses were paid by the Emergency Maternity and Infant Care program of the Children's Bureau. The program, now in its fourth year, is administered by health departments of the states. Wives and infants under 1 year of men serving in the lowest grades of the Army, Navy, Coast Guard and Marine Corps are eligible for care at government expense without regard to family circumstances or racial status. All costs of doctor, nurses and hospitals are paid by the government. At one time the government was paying for between 40,000 and 45,000 maternity cases a month, but the number is down now to about 15,000 a month.

UNRRA Grants Funds to World Health Organization

The United Nations Relief and Rehabilitation Administration has given to the embryonic World Health Organization interim commission a credit of $1,500,000 to carry out UNRRA's health activities, beginning January 1 in Europe and next April in China. The interim commission, meeting in Geneva November 4 to 13, authorized its executive secretary, Dr. Brock Chisholm, to use up to $500,000 of the UNRRA credit in the first quarter of 1947. By a vote of 36 to 0 the Social, Humanitarian and Cultural Committee of the United Nations asked the assembly to recommend that all members ratify the World Health Organization constitution.

Infantile Paralysis Declines in Nation, Attacking 489 During Week

Infantile paralysis was reported by the U. S. Public Health Service to be declining in the nation during the past week, when it afflicted 489 men, women and children, bringing the total of cases up to 23,427 for this year. There were 13,514 cases all of last year and 19,053 in 1944, the worst poliomyelitis year since 1916. The 1946 toll is expected to reach 25,000.

Producers of Streptomycin Ask Removal of Controls on Distribution

The Civilian Production Administration has been asked by the producers of streptomycin to relax distribution controls in order to make larger supplies available to users.

Coming Medical Meetings

American College of Surgeons, Cleveland, Dec. 16-20. Dr. Dallas B. Phemister, 40 E. Erie St., Chicago 11, Secretary.

Southeastern Allergy Association, Atlanta, Ga., Jan. 18-19. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

GOVERNMENT SERVICES

ARMY

NEW COURSE IN PREVENTIVE MEDICINE

A new course in elementary preventive medicine has been opened at the Medical Department Professional Service Schools, Army Medical Center, Washington, D. C., in order to provide preventive medicine officers for the immediate needs of the Army. The five weeks course will consist of lectures, field work and laboratory investigations. The present class comprises 51 students, 34 of whom are newly appointed medical officers. Sixteen Air Corps doctors are in the group. There is one representative from the Ecuadorian army, Capt. Efrain Z. Guerrero.

While much of the instruction will be carried out by the staff of the Army Medical Center and Walter Reed General Hospital, distinguished civilian doctors will lecture as part of the plan in appointing specialists as consultants to the Secretary of War. Among them will be Kenneth Maxcy, Johns Hopkins University; John H. Dingle, Western Reserve University Medical School, Cleveland; Thomas Francis, University of Michigan School of Public Health; Henry M. Thomas, Johns Hopkins University; Martin Frobisher, Johns Hopkins University; Esmond Long, Phipps Institute, Philadelphia; Joseph Stokes, University of Pennsylvania; George Larrimore, National Cancer Research Foundation, New York; John B. Youmans, Vanderbilt School of Medicine; Albert B. Sabin, University of Cincinnati, and Clarence S. Livingood, University of Pennsylvania.

ARMY EPIDEMIOLOGICAL BOARD RECEIVES AWARD

The Army Epidemiological Board was one of five groups in the fields of medical research and public health administration to receive the Lasker Group Award during the annual meeting of the American Public Health Association in Cleveland in November. Dr. Francis G. Blake, dean, Yale University School of Medicine, New Haven, Conn., chairman of the board during the time for which it was cited, accepted the award on behalf of the board. The Army Epidemiological Board was cited for its work in the control of infectious diseases, one aspect of which was its development of an effective vaccine against influenza. In addition to the services of some 125 authorities on infectious diseases, the board enlisted the facilities of some universities and scientific institutes and conducted extensive surveys and experiments in all theaters where American troops were in operation.

Other groups awarded were the Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture; the National Institute of Health, U. S. Public Health Service; the Northern Regional Research Laboratory, Department of Agriculture, and the Board for the Coordination of Malarial Studies. The latter board was composed of representatives of the Army, Navy, Public Health Service, National Research Council, Committee on Medical Research and other civilian organizations engaged in malaria research.

IODINE INSTEAD OF CHLORINE FOR WATER PURIFICATION

A new tablet for purifying water in the soldier's canteen which is considered superior to the chlorine type tablets used during the war, has been announced by the War Department. The new tablet makes the drinking water less objectionable in taste and odor, can be used under a wider range of conditions, and dissolves more quickly than its predecessor. Scientists of the Army Medical Department, Quartermaster Corps and Corps of Engineers, after examining a large number of different compounds, found that triglycine hydroperiodide possessed the best military characteristics. Quickly dissolving tablets containing this chemical, which liberated 7½ parts per million of elemental iodine, were subjected to extensive testing and were found to be safe and highly effective.

Additional tests of the new "tablet, water purification, individual, iodine," as the compound has been designated, will be carried out during the ensuing year.

ARMY AWARDS AND COMMENDATIONS

Colonel John E. Elmendorf Jr.

The Legion of Merit was recently awarded to Col. John E. Elmendorf Jr., M. C., A. U. S., New York, for exceptionally meritorious conduct in the performance of outstanding services as director of the Army School of Malariology from Jan. 14, 1944 to June 3, 1945 and as commandant of the Army School of Malariology from June 4, 1945 to Jan. 25, 1946. The citation states that "his energetic application of foresight, inventiveness, organizing ability and leadership was of inestimable value to the organization's smooth function and constant improvement of the school. Through his intimate and profound knowledge of Central America and his courteous and dignified professional manner, Colonel Elmendorf has been able to obtain the active cöoperation of Alcalded, Corregidores, public health nurses and school teachers in the interior towns of the republic of Panama to carry on malaria surveys and to secure teaching material for the classes attending the Army School of Malariology and to maintain the most cordial relations with the residents of the towns in which the tests were carried out. Colonel Elmendorf's sound judgment, initiative and cheerful attitude under most trying conditions reflect the highest credit to himself and the military service." Dr. Elmendorf graduated from the Johns Hopkins University School of Medicine, Baltimore, and entered the service Dec. 18, 1943.

NUTRITION LABORATORY

Dr. Robert E. Johnson became technical director of the Army Medical Nutrition Laboratory at Chicago on October 1, succeeding Dr. George H. Berryman. Dr. Johnson, who holds a Ph.D. from Oxford and an M.D. from Harvard, has been associated with the Harvard University Fatigue Laboratory since 1935 and has done much research in the field of physiology and nutrition. Dr. Berryman, who holds a Ph.D. from the University of Minnesota, was commanding officer and director of the nutrition laboratory from its activation in 1941 until he left, October 1, to attend the University of Illinois Medical School.

DIRECTOR OF LIBRARY SERVICE APPOINTED

Mr. Francis R. St. John, who during the war was acting librarian at the Army Medical Library and later was chief of the circulation department, New York Public Library, has been appointed director of library service for the Veterans Administration effective Jan. 1, 1947. Mr. St. John will direct the work of more than 150 libraries scattered throughout the United States.

LIBRARIAN RESIGNS

Mr. Wyliss E. Wright has resigned as librarian of the Army Medical Library to become librarian of Williams College, Williamstown, Mass., effective Jan. 1, 1947. Mr. Wright came to the Army Medical Library in 1945 from the New York Public Library, where he was chief cataloguer. From 1930 to 1933 he was librarian at the American Academy in Rome.

CHARGE FOR PHOTODUPLICATION SERVICE

The Army Medical Library, which during the war conducted a free photoduplication and microfilm service on a global basis in the interest of medical research, will make a nominal charge for this service starting Jan. 1, 1947. The volume of this work had increased so much that a revision of policy was recommended by a committee studying the matter under the auspices of the honorary consultants at the request of the Surgeon General. This move will also place the library in line with other federal agencies which charge for similar services. The following price scale has been set up:

Microfilm.—Periodical Articles: A flat charge of 50 cents for any article in a single volume. Books and Serial Publications: Fifty cents for each fifty pages or fraction thereof.

Photoprints.—Fifty cents for each ten pages or fraction thereof from any single volume.

Method of Payment.—All charges are on the basis of cash with order. Only federal agencies are exempted from this requirement. Payment may be made by cash or by check or money order drawn to the Treasurer of the United States.

Order blanks are available on request.

PERSONAL

Brig. Gen. Raymond W. Bliss, Deputy Surgeon General, is making a six weeks tour of army medical installations in Europe. Last year General Bliss inspected all army medical installations in the Pacific Theater, and last spring he returned to Bikini for the atomic bomb test.

PUBLIC HEALTH SERVICE

STANDARDS OF HOSPITAL CONSTRUCTION

The Hospital Survey and Construction Act, authorizing a nationwide program of hospital construction, requires that standards of construction and equipment be established by the Surgeon General, U. S. Public Health Service. These standards will apply to all projects to be built with federal assistance under this legislation.

Such standards have recently been drafted by the Office of Technical Services, Division of Hospital Facilities, U. S. Public Health Service, of which Marshall Shaffer is chief. The Committee on Hospitalization and Public Health of the American Institute of Architects approved the standards and submitted them to a special technical committee on architectural standards appointed by the Federal Hospital Council.

This committee, which met in Washington November 12 and 13, includes in its membership James R. Edmunds, president, American Institute of Architects, chairman; Dr. Claude Munger, director, St. Luke's Hospital, New York; Dr. Frank F. Tallman, Committee of Mental Hygiene, Department of Public Welfare, Ohio; Dr. Warren P. Morrill, Director of Research, American Hospital Association; Dr. Ralph Horton, director, Homer Folks Tuberculosis Hospital, Oneonta, N. Y.; William A. Riley, architect, Boston, and A. N. Langius, director, Building and Construction Division, State Administrative Board, Michigan.

After review and approval by this committee, the standards were accepted by the Federal Hospital Council. These standards will be incorporated in the rules and regulations of the Hospital Facilities Division. The Surgeon General and the federal security administrator will have to approve the rules and regulations before they are published and made available to all persons interested in this program. It is hoped that they will be ready before December 31.

The standards established constitute the minimum requirements considered necessary to insure properly planned and well constructed hospitals and health centers. But since they are minimum requirements, it is pointed out that they should form a basis only for the development of higher standards.

There has been no attempt, in establishing these standards, to make them coincide with all the various state and local codes and regulations. However, strict compliance with all applicable state and local regulations is required. Likewise, compliance is required with minimum standards of construction and equipment promulgated by the state agency administering this program, where such standards are higher than those established by the Surgeon General.

In general, these standards fall into five classifications: site, architectural, structural, mechanical and drawing and specifications. The architectural standards cover the following types of projects: general, tuberculosis, mental psychiatric and chronic disease hospitals; nurses' homes; schools of nursing; public health centers, and state public health laboratories. The mechanical standards cover heating, steam piping and ventilation; plumbing and drainage; electrical; elevators and dumbwaiters; refrigeration; kitchen equipment, and laundry.

DEDICATION OF MEMORIAL LABORATORY

The recent dedication of the new Memorial Laboratory for the study of infectious diseases was attended by medical and civilian dignitaries of the United States, Russia and China. The laboratory, the eighth building of the National Institute of Health at Bethesda, Md., is this country's expression of gratitude for the sacrifices of the twenty-three members of the United States Public Health Service who have died in line of duty. The first of these martyrs was Dr. Roswell Waldo, who succumbed to yellow fever in 1878. Three names were inscribed on this roll of honor as recently as 1944: those of Dr. Richard G. Henderson, fatally infected with scrub typhus, bacteriologist Rose H. Parrott, who died of tularemia, and scientific aide Philip LeRoy Jones, fatally infected with scrub typhus.

The three story brick building, built at a cost of $1,500,000, will be the scene of intensive research on various virus and rickettsial diseases. The building has been planned and constructed to provide maximum safety for the scientists who will carry on this dangerous work. Dr. Charles Armstrong, chief of the Division of Infectious Diseases, National Institute of Health, will administer the new laboratory.

At the ceremony the director of the National Institute of Health, Dr. Rolla E. Dyer, welcomed the more than three hundred guests and introduced the speakers, including Dr. Thomas Parran, Surgeon General, United States Public Health Service; Dr. James Crabtree, Deputy Surgeon General; Dr. Detlev Bronk, chairman, National Research Council; Dr. Vassily V. Parin, secretary general, Academy of Medical Science of the U. S. S. R., and Dr. Szeming Sze, representative, National Health Administration of China.

OFFICERS COMMENDED BY NAVY

Comdr. E. G. Williams and Lieut. Comdr. Howard L. Andrews, both of the U. S. Public Health Service, have been commended by Vice Admiral W. H. P. Blandy, commander, Joint Task Force One, for work in connection with "Operation Crossroads." Commander Williams' assignment called for procurement of radiation detection instruments and radiation sources, which project Admiral Blandy characterized as most difficult. Commander Williams was also praised for establishing the "technical exercise," or instrumentation phase, of the training course. Lieutenant Commander Andrews assisted Commander Williams and also served as instructor in physics and nuclear physics. The admiral declared that Andrews was outstanding in this assignment. Admiral Blandy wrote that the "fine capabilities, initiative, cooperative attitude, technical knowledge and leadership displayed by these officers make them a real credit to the service."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Gift to University Eye Clinic.—The Alabama Sight Conservation Association recently donated $10,000 to the department of ophthalmology of the Medical College of Alabama to provide equipment for the University Eye Clinic. The association was organized April 2, 1944 by the Alabama Lions Clubs, and its funds are derived from club memberships, life memberships, case memberships, contributing memberships and individual memberships; the East-West baseball game played each June in Birmingham sponsored by the Birmingham *News-Age Herald, Esquire* magazine, Alabama Lions and Alabama Sight Conservation Association, Inc.

CALIFORNIA

Personal.—Dr. Frank H. Rodin has resigned as ophthalmologist to the bureau of child hygiene, San Francisco Department of Public Health, a position he held for twenty years. He has been succeeded by Dr. Thomas G. Hall, San Francisco, who graduated at St. Louis University School of Medicine in 1923.——Dr. Norman Reider, Los Angeles, has been appointed chief of the psychiatric clinic at Mount Zion Hospital, San Francisco, to succeed the late Dr. Jacob S. Kasanin, San Francisco.

Cancer Fund Honors Dr. Lynch.—The Frank Worthington Lynch Memorial Fund for Cancer Research was recently established as a perpetual memorial fund to Dr. Lynch, who at the time of his death was professor of surgery and gynecology. The fund will finance special research in the history of cancer started by Dr. Lynch some thirty years ago. Dr. Herbert F. Traut, professor of surgery and gynecology and successor to Dr. Lynch, is in charge of continuing the research under the fund. Other sponsors are Dr. George Ebright, associate clinical professor of medicine emeritus, and Dr. William B. Thompson, Los Angeles.

COLORADO

Dr. Masten Goes to Oregon.—Dr. Alfred R. Masten, Denver, director, division of tuberculosis control, Colorado State Board of Health, Denver, has been appointed to the administrative staff of the Oregon State Board of Health, Portland, newspapers announced October 8.

Dr. Gengenbach Made Professor Emeritus.—Dr. Franklin P. Gengenbach, Denver, has been appointed professor emeritus of pediatrics at the University of Colorado School of Medicine, Denver. He has been a volunteer faculty member with the university medical school since 1911. He had been professor of pediatrics and head of the department from 1930 until his retirement on October 1.

ILLINOIS

Chicago

The Christian Fenger Lecture.—The eleventh Christian Fenger Lecture of the Institute of Medicine and the Chicago Pathological Society will be delivered at the Palmer House on Monday evening, January 13, by Dr. Robert A. Moore, Mallinckrodt professor of pathology and acting dean, Washington University School of Medicine, St. Louis, on "Interpretative Morphology."

Personal.—Dr. Fred L. Adair, emeritus professor of obstetrics and gynecology, University of Chicago, and formerly chief, medical staff, Chicago Lying-in Hospital, has received a grant-in-aid from the U. S. Department of State to enable him to serve as visiting lecturer in obstetrics in Argentina. While in Argentina Dr. Adair will lecture at the universities in Buenos Aires, Cordoba, Santa Fe and La Plata. He has been invited by the Society of Obstetrics and Gynecology of Argentina as a special delegate to the sixth Argentina Congress of Obstetrics and Gynecology.

Special Session on Chronic Illness.—On December 3 the Central Service for the Chronically Ill of the Institute of Medicine of Chicago devoted a special session to a discussion on "What Chicago Is Doing About Chronic Illness." The morning session was devoted to the prevention and control of chronic diseases and the afternoon session to long term care of chronically ill patients. Among the speakers were:

Mr. Leo M. Lyons, director, St. Luke's Hospital, Résumé of the Problems of Chronic Illness.

Dr. Andrew C. Ivy, Chicago, vice president, Chicago Professional Colleges University of Illinois, Chronic Diseases—Research and Medical Education in Relation to Prevention and Control.

Miss Edna S. Newman, director, Cook County School of Nursing, Education of Allied Professional Personnel for the Prevention and Control of the Chronic Diseases and the Care of People Disabled by Them.

Dr. John A. Rogers, executive director, Illinois division, American Cancer Society, Health Education and Community Agencies in Prevention and Control of Particular Diseases.

Dr. Carl Peterson, Chicago, Secretary, Council on Industrial Health, American Medical Association, Rehabilitation of Chronically Ill and Handicapped People.

Mr. Samuel A. Goldsmith, director, Jewish Charities of Chicago, Facilities and Services Needed for Care of Long-Term Patients.

Mr. Frank T. Loomis, executive director, Chicago Community Trust, Financial Aspects of Developing New Facilities.

Mr. Raymond M. Hilliard, public aid director, Illinois Public Aid Commission, Meeting the Costs of Care for Financially Dependent Patients.

Miss Mary E. Westphal, director, Visiting Nurse Association of Chicago, Care of Patients in Their Homes.

Dr. Roger W. De Busk, Evanston, president, Chicago Hospital Council; Rev. A. J. Munsterman, superintendent, Bensenville Home Society, Bensenville, Ill., and Miss Kathleen Cronin, superintendent, White Haven Acres, Glenview, Ill., Development of New Community Facilities for Care of Long-Term Patients.

Miss Edna Nicholson, director, Central Service for the Chronically Ill, The Role of the Central Service for the Chronically Ill.

New Wing for Research and Educational Hospitals.—Construction of a thirteen story wing to the Research and Educational Hospitals, University of Illinois College of Medicine, will begin about March 1. Of the total cost of the addition, $6,300,000, $2,200,000 is available from funds appropriated for the current (1945-1947) biennium. An additional sum of $4,100,000 is included in the university's total budget request for the 1947-1949 biennium for construction on the Chicago Professional College campus. Hospital bed capacity will be increased from 503 to 723 by the addition. At present the university's hospital beds total 227 in the general hospital, 120 in the Illinois Surgical Institute for Children (university orthopedic department) and 156 in the Illinois Neuropsychiatric Institute, which is owned by the department of public welfare but staffed and operated by the university. The thirteen story addition will connect with the present hospital at six levels on the north side and with the one story physical environment addition at one level on the west side. All three will be joined through an extension of the present tunnel system. Department clinical offices, research laboratories, x-ray and other adjunct services and operating rooms will be located on the second through the fifth floors. Floors 6 through 13 will contain hospital beds. Air conditioning will be installed in one of the hospital bed floors designed for 25 patients. The purpose is to provide special research and therapy under controlled temperatures. Operating rooms, delivery rooms and nurseries will also be air conditioned, and all floors will be so constructed that air conditioning may be installed later. The addition will be located on the west side of Wood Street between Polk and Taylor streets between the present hospital and the Illinois Neuropsychiatric Institute.

INDIANA

State Medical Election.—Dr. Cleon A. Nafe, Indianapolis, was chosen president-elect of the Indiana State Medical Association at its recent annual meeting and Dr. Floyd T. Romberger, LaFayette, will take office as president of the association January 1, succeeding Dr. Jesse E. Ferrell, Fortville. Dr. Arthur F. Weyerbacker, Indianapolis, is treasurer for another term. Named as delegates to the American Medical Association were Drs. Homer G. Hamer, Indianapolis, and Alfred S. Giordano, South Bend. French Lick was selected as the site for the 1947 convention.

Grant for Research in Gangrene.—Indiana University School of Medicine has received a grant of $15,000 from the National Institute of Health, U. S. Public Health Service, Bethesda, Md., to study the organisms concerned in the cause of gas gangrene of man and certain animals, according to the Indianapolis *News*, November 8. Leland S. McClung, Ph.D., Bloomington, associate professor of bacteriology, will be in charge of the program, and certain parts of the work will be done in cooperation with Harry G. Day, Sc.D., Bloomington, associate professor of chemistry.

MARYLAND

Lecture Named for Julius Friedenwald.—On November 14 Dr George B Eusterman, Mayo Clinic, Rochester, Minn, gave the first annual Dr Julius Friedenwald Memorial Lecture at the University of Maryland School of Medicine, Baltimore His subject was "Newer Phases of Gastroduodenal Ulcer" The Friedenwald Lecture was established at the University of Maryland School of Medicine in Baltimore in 1941, following the death of Dr Friedenwald, professor emeritus of gastroenterology at the Maryland medical school

Institute for Mental Disorders.—Dr Robert V Seliger, Baltimore, has been named medical director of the newly organized Neuropsychiatric Institute of Baltimore, with headquarters at 2030 Park Avenue, Baltimore 17 The institute is a private outpatient arrangement for the investigation, understanding and treatment of nervous, mental, emotional and personality illnesses In addition to the usual investigative and treatment technics, the institute is equipped with an electroencephalographic laboratory and has trained personnel to administer the various practical clinical psychologic test technics Electric shock therapy is available for carefully selected patients While the institute itself does not provide hospitalization, facilities are available to arrange for the care of patients requiring partial semi or complete protective environment

MICHIGAN

Changes in Health Personnel—Dr William B Wild, Mansfield Ohio, has been named director of the Barry County Health Department, filling the vacancy that occurred when Dr John K Altland, Hastings, resigned to become director of local health services of the Michigan State Department of Health, Lansing

Dr. Cummings Goes to Ireland—Dr George D Cummings, director of laboratories, Michigan State Department of Health Lansing, was to leave November 9 for Dublin to direct an Irish Free State campaign against epidemic diarrhea in newborn infants, newspapers reported Specimens requiring analysis will be flown from Ireland to Michigan, permitting examination in the Lansing laboratories twenty hours after the specimens are collected

NEW YORK

Louise Beamis Resigns—Dr Louise W Beamis has resigned as secretary of the Medical Society of the County of Erie effective January 1, owing to illness of a member of her family Dr Beamis had held the secretaryship since 1929

Buffalo Cancer Center.—Plans to establish a cancer center in Buffalo and the award of nineteen fellowships and grants totaling $135,455 for cancer research were announced November 6 by John Pennington, president of the state division of the American Cancer Society The cancer center is to be used as a directional clinic to aid in early detection and arrest of the disease but will not be used for research or treatment The fellowships and grants went to different hospitals, universities and other groups for work by specified individuals

New York City

The Third Harvey Lecture—Dr Charles B Huggins, professor of surgery (urology), University of Chicago School of Medicine, will deliver the third Harvey Society Lecture in the current series at the New York Academy of Medicine, December 19 His subject will be "The Prostatic Secretion"

Perkin Medal Goes to Robert Williams—Robert R Williams D Sc, director of research of the Research Corporation of New York, has won the 1946 Perkin Medal of the American section of the Society of Chemical Industry, according to the New York *Times*, November 25 The medal will be presented January 10

Public Exhibit on Anesthesia—Commemorating the hundredth anniversary of the discovery of ether, New York University College of Medicine opened to the public November 13 an exhibit on anesthesia in the library of the college at 477 First Avenue Old and rare items connected with the history of anesthesia were on display until November 27

New Professor of Surgery at Columbia—Dr John S Lockwood since 1924 chief of the division of surgery, committee on medical research of the Office of Scientific Research and Development has been appointed professor of surgery at Columbia University College of Physicians and Surgeons Dr Lockwood will also serve as attending physician at the Presbyterian Hospital Dr Lockwood, who graduated at Harvard Medical School, Boston, in 1931, has for the past two years been associate professor of surgery at Yale University School of Medicine New Haven, Conn

SOUTH CAROLINA

Changes in Health Officers—Dr Charles I Goodwin, Holly Hill, was appointed to succeed the late Dr Grover C Bolin as director of the Orangeburg and Calhoun County Health Departments, September 1 Dr Caroline H Callison, Chatham, has been granted a leave of absence as director of the Greenwood and McCormick County Health Departments to take a course in public health at Columbia University During her absence Dr Maulden J Boggs Jr, health officer of Abbeville, will be in charge of the Greenwood and McCormick health units

TEXAS

Postgraduate Assembly.—The postgraduate medical assembly of South Texas was held in Houston, December 3 5 Included among the speakers were

Dr Eugene F Traub New York Dermatology
Dr Henry L Bockus Philadelphia, Gastroenterology
Dr Deryl Hart, Durham, N C, Surgery
Dr Richard W TeLinde Baltimore, Gynecology
Dr Guy A Caldwell New Orleans Orthopedics
Dr Lowrain E McCrea Philadelphia Urology
Dr Paul H Holinger, Chicago, Laryngology
Dr Frederick H Falls Chicago, Obstetrics and Gynecology
Dr James L Wilson Ann Arbor, Mich Pediatrics
Dr Wendell L Hughes Hempstead N Y, Ophthalmology
Dr Fletcher D Woodward Charlottesville, Va, Otolaryngology
Dr Sidney A Portis Chicago Medicine
Dr Edwin Hayden, Boston, Surgery
Dr Thomas D Allen, Chicago, Ophthalmology

University News—Dr George M Decherd Jr, Galveston, has been appointed director of the student health service of the University of Texas at the Austin campus He is relinquishing his positions at the medical branch at Galveston as director of the heart station and as director of the postgraduate training program but is retaining his title as professor of medicine Dr Truman G Blocker Jr, Galveston, professor of surgery, has been appointed director of the postgraduate training program at Galveston——Dr Robert W Davis, formerly associated with the department of psychiatry of the University of Colorado School of Medicine, Denver, has been appointed associate professor of neuropsychiatry at the University of Texas Medical Branch Galveston, and assistant director of the Galveston State Psychopathic Hospital Dr Davis graduated at the University of Michigan Medical School, Ann Arbor, and received special training in psychiatry at the University of Colorado School of Medicine

VIRGINIA

Division Heads Named—Dr J C Neale Jr, Norfolk, assistant director of the bureau of local health services, Virginia State Department of Public Health, has been named director and Dr Peyton M Chichester, Richmond, also an assistant director has been chosen acting director of the bureau of tuberculosis outpatient service and crippled children's service The Richmond *Times-Dispatch* reported on October 26 that both appointments were effective immediately Dr Jack B Porterfield who recently resigned as health officer of Richmond, effective November 15, will return to the state board of health as an assistant director in the bureau of local health services He has been succeeded in the Richmond position by Dr Charles Howe Eller Baltimore

WEST VIRGINIA

Personal—Dr Andrew E Amick of Lewisburg has been named by Dr Newman H Dyer, state health commissioner, as district health officer and pediatric consultant for district number 2, composed of Greenbrier, Pocahontas and Monroe counties Headquarters will be set up at Lewisburg With the announcement of the appointment of Dr Amick the commissioner said that the state health department is now working out details for a branch laboratory which, it is hoped, can be established and operated at Lewisburg under the supervision of Dr Amick Plans are still in the formative stage, but it is expected that the laboratory can be opened shortly after the first of the year There has been a vacancy in the office of district health officer for district number 2 since 1944, when Dr Herbert Duncan resigned to accept a residency in eye, ear, nose and throat at the Nashville General Hospital in Nashville

——Dr. Charles Taylor, Huntington, has been reappointed superintendent of the Huntington State Hospital, a position he has held since 1933——Dr. Harry F. Coffman, Keyser, has been named by the Public Health Council as part time health officer for Mineral County.

WISCONSIN

The Loevenhart Memorial Lecture.—Dr. Walter C. Alvarez, Rochester, Minn, delivered the Dr Arthur S. Loevenhart Memorial Lecture, December 5, at the University of Wisconsin Medical School, Madison, under the auspices of the Phi Delta Epsilon Medical Fraternity Dr Alvarez's subject was "Headache"

GENERAL

Dr. Foote Joins Society for Prevention of Blindness.—Dr Franklin M Foote, recently discharged from service in the Army of the United States, has been appointed medical director of the National Society for the Prevention of Blindness, 1790 Broadway, New York 19 Dr Foote retains his position as assistant professor of public health and preventive medicine at Cornell University Medical College

New Journal on Postgraduate Medicine.—The official publication of the Inter-State Postgraduate Medical Association of North America will be published beginning January 1947, announces Dr Arthur G. Sullivan, managing director of the Interstate Postgraduate Medical Association of North America The business manager, Paul K Whipple, who is located at 515 Essex Building, Minneapolis, is already receiving space commitments for the first issue The subscription price is $8 per year

Vitamin Foundation Approves Grants.—The National Vitamin Foundation at its first dinner meeting at the Waldorf-Astoria Hotel, November 15, announced that it had approved six grants-in-aid, totaling $23,300 The new grants include

Willard A Krehl, Yale University School of Medicine $2 000, alteration of vitamin requirements induced by natural foodstuffs

Barnett Sure, Ph D, professor of agricultural chemistry, University of Arkansas, Fayetteville, $3,000, influence of the various components of the vitamin B complex on protein utilization

Dr James J Smith, assistant in medicine New York University College of Medicine, $1,500, determinations of biochemical base lines for studies of vitamin hormone interrelationships

Dr William J Darby, assistant professor of biochemistry and medicine, and Dr Edgar Jones, associate professor of clinical medicine Vanderbilt University School of Medicine, Nashville, $3,800 the hemopoietic activity and other physiologic properties of the vitamin M group of substances

Dr Tom D Spies, associate professor of medicine, University of Cincinnati College of Medicine, $5,000, relation of nutrients to white blood cell formation

Max K Horwitt Ph D Elgin State Hospital, Elgin, Ill, $8,000, study of riboflavin in human nutrition

New Psychiatric Foundation.—The organization of the Psychiatric Foundation has been announced The group is being developed by the American Psychiatric Association and sponsored by the American Neurological Society Dr Leo H Bartemeier, Detroit, secretary of the American Psychiatric Association, is in charge of the group designated by the association to assume responsibility for the new foundation during the organization period Objectives. education of members of the psychiatric team in the psychiatric field; psychiatric research, medical legislation; child psychiatry, education of the public, and policy as to fund raising In addition to Dr Bartemeier the organization committee includes Drs. Edward A Strecker, Philadelphia, Frederick Parsons, New York; Karl M Bowman, San Francisco; Arthur H. Ruggles, Providence, R I; Winfred Overholser, Washington, D. C, Harry C Solomon, Boston; Gregory Zilboorg, New York City, C. Charles Burlingame, Hartford, Conn; Mesrop A Tarumianz, Farnhurst, Del, and Mr. D. Walker Wear, New York Austin M Davies is executive director, and headquarters are in room 924, 9 Rockefeller Plaza, New York

Directory of Convalescent Homes.—The Committee on Public Health Relations of the New York Academy of Medicine is preparing a new edition of the "Directory of Convalescent Homes in the United States," to be published by the Sturgis Fund of the Winifred Masterson Burke Relief Foundation of White Plains, New York. The last issue of this directory was published by the Sturgis Fund in 1931 under the auspices of the Committee on Convalescent Care of the American Conference on Hospital Service and has long been out of print. Early in January a questionnaire will be distributed to all recognized convalescent homes maintained by municipalities, counties or voluntary bodies The information sought deals with the physical plant, the staff, the requirements for admission, the type of patients, therapy and such other matters as will make the directory a dependable guide for physicians who wish to refer their patients to institutions for convalescence. The questionnaire is so devised that it can be filled out with a minimum of effort. Convalescent homes that do not receive a questionnaire are urged to request one by writing to E H. L Corwin, Executive Secretary, Committee on Public Health Relations, New York Academy of Medicine, 2 East 103d Street, New York 29.

Borden Award in Nutrition.—The American Institute of Nutrition will present the Borden Award in recognition of distinctive research by investigators in the United States and Canada which has emphasized the nutritive significance of the components of milk or of dairy products. The award will be made primarily for the publication of specific papers, but the judges may recommend that it be given for important contributions over an extended period of time. The award may be divided between two or more investigators Employees of the Borden Company are not eligible for this honor The formal presentation will be made at the annual meeting of the institute in Chicago, May 18-22, 1947. To be considered for the award, nominations must be in the hands of the chairman of the nominating committee by Jan. 15, 1947. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate consideration for the award. The chairman is Genevieve Stearns, Ph D, State University of Iowa College of Medicine, Iowa City

Research Council to Study Pollen Distribution.—A research council to study pollen distribution throughout the nation in an effort to help present sufferers from hay fever is being set up by the American Academy of Allergy, the New York *Times* reported November 26. The plan calls for the formation of three major divisions to deal with aero-allergens, foods and drugs and pharmaceuticals The work of the council will be modeled after the Committee on Aerobiology of the National Research Council. Members of the council are to be appointed by the executive committee of the academy in December The first subject to be studied will be air borne substances causing allergies Subcommittees will deal with four major divisions of allergens—pollens, molds, dust and miscellaneous allergens, and air processing Among the projects the subcommittees will prepare will be a daily pollen count map to be made in cooperation with the United States Weather Bureau The map will be offered to newspapers for publication. The academy has allocated $1,000 for initial administrative expenses of the new group Additional financing will be sought from foundations and private contributors.

Francis Amory Prize.—In compliance with the terms of a gift under the will of the late Francis Amory, Beverly, Mass, the American Academy of Arts and Sciences offers a substantial prize for meritorious work addressed to the alleviation or cure of diseases affecting human reproductive organs The gift provides a fund the income of which may be awarded at seven year intervals "as a prize and gold medal, or other token of honor or merit," to any individual or individuals for work of "extraordinary or exceptional merit" in this field In case there has appeared work of a quality to warrant it, the next award will be made in 1947. Awards will be made for what in the judgment of the Committee on the Amory Fund appears to be the most distinctive contribution or contributions in the field as outlined and as based on published work and recognized accomplishment for the current seven year period No formal applications and no essays or treatises from individuals are solicited, but suggestions will be welcome from any appropriate source that will be of aid to the committee in making a wise selection Recommendations may be addressed to Secretary, Amory Fund Committee, American Academy of Arts and Sciences, 28 Newbury Street, Boston

Marriages

John Kellam Lingo, Pungateague, Va., to Miss Hilda Sinclaire Jervis of Marshall, N C, in New York August 14.

John J. Archinard Jr., New Orleans, to Miss Zelma Claudia Weaner of Shreveport, La., April 13.

Robert B. Robertson, Presque Isle, Maine, to Mrs. Ellen Pegues Godfrey in New York recently.

August H. Kramm, Washington, D. C., to Miss Margaret Cotter in Rockville, Md, recently.

Burton Sinclair Wilt to Miss Frances Dowling, both of Wing Point, Wash., September 10.

Frank Cole, Duluth, Minn, to Miss Doris Cohen of Superior, Wis, August 31.

Deaths

Alice Stone Woolley ® Poughkeepsie, N. Y.; born in Yankton, S. D., Sept. 12, 1882; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1930; interned at the Gallinger Municipal Hospital in Washington, D. C., where she was resident physician at the Children's Hospital; past president and chairman of the international relations committee of the American Medical Women's Association; past president and vice president of the Women's Medical Society of New York State; decorated by the French government in recognition of her two years of military service overseas during World War I; appointed by Governor Dewey to the board of visitors of the New York State Training School for Girls, Hudson; served as director of the Dutchess County Health Association, a member of the council of the Dutchess County Girl Scouts and the board of directors of the Dutchess County chapter of the American Red Cross; director of physical education at the local Y. W. C. A. from 1908 to 1925; member of the courtesy staffs of the Northern Dutchess Health Service Center, Rhinebeck, St. Francis and Vassar Brothers hospitals; member of the board and vice president of the Bowne Memorial Hospital; on the board of the Samuel and Nettie Bowne Hospital; medical consultant for Bard College, Annandale-on-Hudson; associate editor of the *Journal of the American Medical Women's Association;* died in the Doctors Hospital, New York, November 16, aged 64, of coronary thrombosis and bronchopneumonia.

Marion Hague Rea ® Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1915; born in Denver July 21, 1885; served an internship at the Philadelphia General Hospital (Blockley Hospital) 1915-1916 and as assistant physician at the Boston Psychopathic Hospital, 1916-1917; returned to Philadelphia to become chief resident physician of the Hospital of the Woman's Medical College of Pennsylvania, in which capacity she served for one year and later assistant and associate in medicine, serving from 1917 to 1923; resident physician at Bryn Mawr (Pa.) College from 1918 to 1920 and in 1923 and 1924; assistant visiting physician to the Philadelphia General Hospital from 1917 to her death; served as instructor in medicine at the University of Pennsylvania School of Medicine since 1918; medical director in the department of physical education for women at the University of Pennsylvania from 1921 to 1935; since 1922 chief in medicine at the Woman's Hospital; died suddenly November 1, aged 61, of myocarditis.

Irving Samuel Haynes ® Plattsburg, N. Y.; born in Saranac, N. Y., Aug. 29, 1861; University of the City of New York Medical Department, New York, 1887; professor of clinical surgery emeritus at Cornell University Medical College, New York; fellow of the American College of Surgeons; served as medical superintendent of the Physicians Hospital, where he has been a member of the board of directors since 1944; consulting surgeon to the Reconstruction and Harlem hospitals in New York and the Glens Falls (N. Y.) Hospital; author of "Practical Guide for Beginners to the Dissection of the Human Body" and "Manual of Anatomy"; received the doctor of science degree from Wesleyan University in 1915; died October 9, aged 85.

William Schaeffer Bertolet ® Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; first president of the Diplomates' Association of Berks County Physicians; served as chairman of the Berks County Medical Advisory Board during World War I; held honorary degrees of doctor of science from Albright College and Franklin and Marshall College; medical director of the Reading Hospital, where he served for many years in various capacities and where he died October 9, aged 71, of heart disease.

Charles James Roach, Zanesville, Ohio; Ohio State University College of Medicine, Columbus, 1917; member of the American Medical Association; won many decorations for outstanding and meritorious service during World War I; company physician for the American Rolling Mill Company, Firestone Tire and Rubber Company and Zanesville Aerie of Eagles, receiving a congressional certificate of merit for his services in this capacity during World War II; served as chief of the staff of the Good Samaritan Hospital, where he died September 21, aged 56, of leukemia.

Ernest E. Billings, Kingston, N. Y.; University of the City of New York Medical Department, New York, 1884; member of the American Medical Association; on the staffs of the Benedictine and Kingston hospitals; died October 4, aged 87, of chronic myocarditis.

George Houghton Bodley ® New Britain, Conn.; Yale University School of Medicine, New Haven, 1907; served on the staff of the New Britain General Hospital; died July 12, aged 66, of pneumonia.

Herschel Baker Bray, Wrightsville, Ga.; Emory University School of Medicine, Atlanta, 1922; member of the American Medical Association; interned at the Grady Memorial Hospital in Atlanta; served during World War I; died July 2, aged 51.

Hiester Bucher ® Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; served on the staff of the Reading Hospital; died August 1, aged 74, of coronary occlusion.

William Roy Cain, Tyler, Texas; University of Texas School of Medicine, Galveston, 1909; member of the American Medical Association; served in France during World War I, for which he received the Purple Heart and was cited for meritorious service by both French and United States commanders; for two and half years ophthalmologist with the U. S. Army induction station at Tyler; for many years city health officer; found dead August 11, aged 59, of coronary occlusion.

Enoch J. Cook, Monahans, Texas (licensed in Texas under the Act of 1907); for two years served with the Selective Service Board; died August 7, aged 69, of cerebral hemorrhage.

Linus Reed Cranmer ® Steubenville, Ohio; University of Michigan Medical School, Ann Arbor, 1915; interned at the Lakeside Hospital in Cleveland; resident physician for the Wheeling Steel Company and the Pennsylvania Railroad; on the staffs of the Ohio Valley and Gill Memorial hospitals; died September 17, aged 56, of coronary thrombosis.

Carl Frederick Dick, St. Louis; University of Nashville (Tenn.) Medical Department, 1901; founder of the Dick-X-Ray Company; died in the Barnes Hospital October 20, aged 68, of coronary disease.

John Henry Donovan, Lowell, Mass.; College of Physicians and Surgeons, Boston, 1905; died September 10, aged 65, of cerebral hemorrhage.

Lee Bennett Gardner, Geneva, N. Y.; Eclectic Medical College, Cincinnati, 1899; member of the American Medical Association; on the staff of the Geneva General Hospital, where he died September 1, aged 73, of ruptured gastric ulcer.

Robert Willis Hatch, Indianapolis; University of Minnesota Medical School, Minneapolis, 1932; diplomate of the National Board of Medical Examiners; died in the City Hospital September 8, aged 40, of portal cirrhosis.

Robert G. Henderson, Falls City, Neb.; Kansas City Medical College, 1900; member of the American Medical Association; affiliated with Our Lady of Perpetual Help Hospital; died September 25, aged 74, of coronary thrombosis.

Henry Francis Kinsman ® Hamlet, N. C.; University of Vermont College of Medicine, Burlington, 1894; died in the Memorial Hospital, Charlotte, August 24, aged 74, of pneumonia.

Charles E. Mays, San Angelo, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1885; honorary member of the State Medical Association of Texas; past president of the Tom Green County Medical Society; served on the staffs of St. John's Hospital and the Shannon West Texas Memorial Hospital, where he died June 20, aged 84, of pneumonia.

Thomas J. Pennebaker, Cotton Plant, Miss. (licensed in Mississippi in 1891); died September 12, aged 87, of arteriosclerosis.

Henry Ruffu, Atlantic City, N. J.; Chicago Medical School, 1928; died in the Atlantic City Hospital September 23, aged 48.

Franklin Wesley Sells ® Osceola, Iowa; Drake University Medical Department, Des Moines, 1896; died September 27, aged 73, of cerebral hemorrhage.

Anthony Claudius Thiolliere, North Little Rock, Ark.; Université de Lyon Faculté de Médecine et de Pharmacie, France, 1894; Dallas Medical College, 1903; member of the American Medical Association; a captain in the medical corps of the U. S. Army during World War I; died September 2, aged 73, of cerebral hemorrhage and hypertension.

Lawrence Patrick Tully, Iron River, Michigan; Marquette University School of Medicine, Milwaukee, 1923; served during World War I; died in the Veterans Administration Hospital in Milwaukee, July 26, aged 49, of pulmonary tuberculosis.

William Morris Watkins, Louisville, Ky.; Kentucky University Medical Department, Louisville, 1904; served during World War I; died in St. Anthony's Hospital September 16, aged 73, of pneumonia complicating cerebral hemorrhage.

The British Medical Association and the National Health Insurance Act

The national health service bill has become law, but the opposition of the British Medical Association has only reached its climax. The association has posted voting forms to all doctors on the medical register asking them to answer Yes or No to the question "Do you desire the negotiating committee to enter into discussions with the minister on the regulations authorized by the National Health Service Act?" They are asked to return the form by November 30 or as soon as possible if in practice oversea. They are asked to state the number of years since qualification and the branch in which they practice. On the plebiscite form they are informed that the time has now come for a crucial decision of the profession. The act authorizes the minister of health now to proceed to regulations dealing with a wide variety of subjects, including the mode of and amount of professional remuneration, the terms and conditions of service generally and the composition of the regional hospital boards. The immediate issue which confronts the profession is whether it will or will not enter into discussions with the minister on the subject matter of these regulations. This issue the association places before the profession as a whole to determine by plebiscite. Those who hold that, notwithstanding the divergence between the principles of the profession and the provisions of the act, discussions should be entered into will answer Yes to the appended question. A decision to enter into discussion does not involve a decision to enter the service. Those who hold that, because of the wide divergence between the principles of the profession and the provisions of the act, the profession should decline to accept service under the scheme, whatever the conditions, will not authorize discussions and will answer No. If a sufficient number give a negative answer, the association will take the necessary action and prepare for the inevitable conflict. Implicit in such a vote is an undertaking, if so advised by the association, not to enter the new service.

The plebiscite form is accompanied by a letter from Dr. Hill, the secretary of the British Medical Association, which summarizes the more important issues on which the Representative Body differed with the government scheme: 1. There should be no control over doctors with regard to the area in which they wish to practice. 2. The transference of hospitals to state ownership was not approved. 3. It is essential to the freedom of the patient and of the profession that doctors should retain the good will of their practices. 4. Remuneration should be by capitation payments. 5. Any doctor, whether a specialist or a general practitioner, must have all the facilities for treating patients that are now held. The plebiscite form is also accompanied by a summary of the act and a report of the negotiating committee of the profession showing the main divergencies of the act from the views expressed by the organized bodies of the profession.

Paludrine in Malaria

At the Royal Society of Tropical Medicine and Hygiene, Professor Hamilton Fairley described remarkable results from the treatment of malaria by the new drug paludrine in the Australian army campaigning in the southwestern Pacific. The medical research unit of the Australian army experimentally infected with malaria 850 healthy volunteers. More than 200 were treated with paludrine, a biguanide derivative, while many hundreds of troops with relapsing benign tertian malaria were treated with the drug under controlled conditions. While taking 100 mg. of paludrine daily for three weeks after being infected with Plasmodium falciparum by infected mosquitoes, volunteers did not develop any symptoms of malaria and parasites were never demonstrated in their blood either microscopically or by subinoculation into fresh volunteers. Thus the drug acted as a causal prophylactic in falciparum infections. After infection with Plasmodium vivax a similar result was obtained. But on ceasing to take the paludrine all those infected subsequently developed delayed attacks of overt vivax malaria. Thus paludrine acted only as a partial prophylactic against benign tertian infections. Volunteers received as many as 130 P. falciparum and 120 P. vivax infections while taking 100 mg. of paludrine daily. During this time they were subjected to severe stresses and strains, including long marches in a tropical climate, chilling by exposure in a freezing chamber and injections of epinephrine and insulin. The daily dose of paludrine was continued for four weeks after the last exposure to infection, which covered a period of two months. Throughout the period of three months no symptoms of malaria were observed and parasites were never demonstrated in the blood. Some twenty-four to thirty-three days after the last dose of paludrine overt vivax malaria developed, but never falciparum malaria.

The practical conclusion from these and other experiments is that paludrine 100 mg. twice weekly will entirely prevent falciparum infection and will suppress vivax malaria throughout the period of administration. The significant quality of paludrine as a schizonticide is the smallness of the dose required to resolve a clinical attack of malaria. A single tablet of 100 mg. will cause disappearance of symptoms and of parasites from the blood, but radical cure is not to be expected from this dose. An entirely new field in the chemotherapeutic control of malaria is opened up by paludrine.

BRAZIL

(From Our Regular Correspondent)

São Paulo, Nov. 22, 1946.

Etiology and Treatment of Arterial Hypertension

Dr. Francisco Xavier de Pinto Lima and Dr. José Engelberg call attention to the factors which assume a role in essential hypertension as well as to the modern conception of that condition such as the phenomena of humoral factors with a predominantly renal origin. There are in the circulation humoral complexes which are formed or stored in different organs of hypertensive and hypotensive patients.

Dr. Lima and Dr. Engelberg present the details of organotherapy in hypertension. To strengthen their point of view they present graphs made in experiments on animals.

Hodgkin's Disease

Based on previous studies and his own observations, Professor Alexandre Donati states that Hodgkin's disease is an infectious reticuloendotheliosis and the infectious agent is the virus discovered by Gordon. The allergic state which develops in the patients is used by Dr. Donati for an intradermal test with diagnostic finality. Dr. Donati points out the advantages of vaccination therapy over roentgen therapy.

Hospitals in Brazil in 1943

In 1943 Brazil had 1,575 hospitals with a capacity of 117,304 beds. The states that have more hospitals are São Paulo with 377, Minas Geraes with 259, Rio Grande do Sul with 250, Distrito Federal with 107, the state of Rio de Janeiro with 92, Paraná with 91, Santa Catarina with 72, Baía with 66 and Pernambuco with 42; the other states have less than 30 hospitals.

POSTGRADUATE CONTINUATION COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

Compiled by the Council on Medical Education and Hospitals for Period Jan. 1, 1947 to July 15, 1947

Medical schools, hospitals, state medical societies and other medical educational institutions and organizations are providing the Council with a growing body of information on courses designed primarily to meet the needs of returning medical officers. These have been incorporated into the lists on these pages. They are not specifically designated for veterans, since most if not all of them may also be open to interested civilian physicians. Furthermore, all courses listed which were not designed primarily for physician veterans are also open to qualified returning medical officers.

Note that each course is listed only once, without cross indexing, so that in some instances a prospective student should look under more than one heading for a desired course.

12. No charge for physicians on active duty in armed forces.
13. $45 00 for 5 days.
14. Or pro rated.
20. For medical officers only.

(To be concluded next week)

Correspondence

LEPROSY

To the Editor —Commenting on the letter of Dr Cristobal Manalang of San Lazaro Hospital, Manila, P I, in The Journal, October 19, page 407, the main points of special interest which he considers are that (1) the essential cause of leprosy is a "virus" stage of Mycobacterium leprae, (2) the disease is contracted up to the age of 4 years by frequent and prolonged contact and (3) microscopically negative as well as positive cases serve to transmit the disease He remarks that if his views are sound they should lead to revision of public health procedures in leprosy by focusing efforts on the protection of children Dr Manalang suggests a study of children of leprous persons in the United States, and he points to the advantage of studying the disease in this country rather than in foreign fields

As to Dr Manalang s views relating to the "virus' stage of M leprae, judgment must be reserved To one who has seen a number of persons unquestionably infected during adult life the emphasis on childhood infection seems too strong One is prepared to consider sympathetically the view that all types of cases may be communicable, though this is contrary to the usual opinion That the public health management of leprosy needs "humanizing,' as Dr Manalang puts it, is obvious to any serious student of the problem Indeed, current practice, under American jurisdiction, is based too much on misinformation and too little on established facts The problem of control must be considered for each area separately on the basis of experience, for example measures that might be justified in areas where the disease spreads fairly freely, as Hawaii or the Philippine Islands, would be unnecessary in the greater part of the United States, where the disease shows little or no tendency to be communicable

Of special interest to dermatologists is Dr Manalang s assertion that the early lesions of leprosy are likely to be confused with those of lupus erythematosus, tuberculosis, syphilis or Boeck s sarcoid While these conditions may on superficial study be mistaken for leprosy or vice versa, the laboratory tests that should always be made would speedily confirm or exclude a diagnosis of leprosy, since the conditions mentioned would be likely to be confused only with the form of leprosy that yields characteristic microscopic findings The proposal that the subject deserves study by the Section on Dermatology and Syphilology of the American Medical Association merits friendly consideration

G W McCoy M D, New Orleans

COLD PACKS FOR PREVENTION OF MUMPS ORCHITIS

To the Editor —In reference to the communication from Novak in The Journal, October 26, page 472, suggesting that cold packs would be a protection for the testes in the orchitis of mumps, it should be pointed out that the pathologic process in mumps orchitis" is apparently an acute hydrocele which causes secondary strangulation edema fibrosis and atrophy of the testis rather than a true testis inflammation

Incision and drainage of the acute hydrocele immediately relieves the pressure on the testis and protects it from further strangulation atrophy A series of cases treated in this manner was reported by Robert A Burhans in the *Journal of Urology* 54 547 (Dec) 1945

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore

146:637-766 (Aug.) 1946

- Theoretical Study of Composition of Alveolar Air at Altitude. W. O. Fenn, H. Rahn and A. B. Otis.—p. 637.
- Effect of Hemorrhage on Plasma Amino Nitrogen of Dog. D. L. Kline.—p. 654.
- Effect of Infusion of Renin on Flow and Protein Content of Lymph of Anesthetized Dogs. Florence W. Haynes and Esther Hardenbergh.—p. 666.
- Influence of Hepatectomy on Relative Concentrations of Protein Components of Dog Plasma as Determined by Electrophoresis. Muriel Platt Munro and Annabel Avery.—p. 673.
- Effect of Intra-Arterially Injected Adrenalin on Blood Flow, Sugar Retention and Lactate Output of Leg Tissues of Anesthetized Cats. F. R. Griffith, Julia E. Lockwood and T. A. Loomis.—p. 677.
- Dark Adaptation of Color Anomalous. A. Chapanis.—p. 689.
- Effect of Para-Aminopropiophenone Induced Methemoglobinemia on Oxygenation of Working Muscle in Human Subjects. J. Tepperman, O. Bodansky and B. J. Jandorf.—p. 702.
- Respiratory Metabolism of Human Subjects During Prolonged Exposures to Simulated Altitudes of 8,000 and 10,000 feet. S. A. D'Angelo.—p. 710.
- Pyridoxine Deficiency in Dogs as Affected by Level of Dietary Protein. Agnes Fay Morgan, Mary Groody and Helen E. Axelrod.—p. 723.
- Simultaneous Determinations of Blood Volume by Co and Dye (T 1824) Under Various Conditions. W. S. Root, F. J. W. Roughton and M. I. Gregersen.—p. 739.

American Journal of Public Health, New York

36:963-1104 (Sept.) 1946

- *Illumination Standards. M. A. Tinker.—p. 963.
- Recent Developments in Murine Typhus Fever Control. J. S. Wiley.—p. 974.
- Race Relations in Community Health Organization. P. B. Cornely.—p. 984.
- Health Education Program in Puerto Rico. Alice Miller Johnson.—p. 993.
- Modern Treatment of Syphilis. E. W. Thomas.—p. 1002.
- *Refrigeration in Food Control Program. H. S. Adams.—p. 1007.
- What Good Are Health Museums? B. Gebhard.—p. 1012.
- Appraisal Forms and Sanitation Standards Used in Michigan Community Health Project. H. J. Dunsmore.—p. 1016.
- Gonococcus Examinations: Comparison of Slides, Mailed Slants and Immediate Plates. Grace Eldering and Evelyn Palser.—p. 1023.
- *Dangers Associated with Use of Living "Attenuated" Typhus Vaccine. J. F. Sadusk Jr. and H. Kuhlenbeck.—p. 1027.
- Place of Entomologist in Public Health. T. A. Olson.—p. 1031.
- Use of Chlorine Dioxide in Water Treatment. G. P. Vincent and J. F. Synan.—p. 1035.

Illumination Standards.—Tinker points out that codes of lighting have been issued by the Illumination Engineering Society either alone or jointly with the American Institute of Architects. He thinks that more satisfactory approach to hygienic lighting might be achieved by coordinating the work of engineers, physiologists and psychologists. It is obvious that visual work should not be done at critical levels of illumination. There should be an adequate margin of safety to provide for individual variation. For such visual tasks as reading good sized print (10 to 11 point) on a good quality paper, 10 to 15 foot candles should provide hygienic conditions when one's eyes are normal. For the reading of newsprint, 15 to 20 foot candles should be adequate. In situations involving the reading of handwriting and other comparable tasks, 20 to 30 foot candles seems desirable. For tasks comparable to discrimination of 6 point type there should be 30 to 40 foot candles. For the most severe tasks encountered in workday situations 40 to 50 foot candles will be found adequate. There is no valid experimental work now available that indicates a need for over 50 foot candles intensity for adequate visual discrimination. These suggestions hold for school children as well as for adults. Intensity of illumination cannot be prescribed without coordinating it with other factors such as distribution of light and brightness contrast.

Refrigeration for Food.—In a survey of 300 restaurants, Adams found that the refrigerator temperature in 26 per cent of them exceeded 50 F. While 50 F. is generally accepted as the maximum allowable temperature for the storage of many perishable foods, a temperature several degrees lower is preferable. For fresh meat a range of 35 to 40 F. is recommended, and for poultry 29 to 32 F. Food should not be stored on top of cooling units or on the drip pan below the unit, since such a practice restricts air circulation and may contribute to frosting of the unit. Refrigerator shelves should not be covered with paper, linoleum or similar material, since this causes stagnation of air, creates excessive sweating of products and increases operating expense. Fresh meat should be stored so there is a complete circulation of cool air around it. Placing large amounts of food in a single container should be avoided. Ultraviolet light in conjunction with refrigeration is used mainly as an inhibitor to microbic growth. Reduction of air borne infection and removal of objectionable odors from cold storage boxes is also claimed when ultraviolet light is used. Ultraviolet rays have little penetrating power, so that even very thin films of dirt or moisture may shield the micro-organisms from the damaging effect of the radiation. The question of rancidity must also be recognized. Butter, cream, lard and fat sausages exposed to direct radiation will become rancid and must be protected by storing in a covered container. Fats or fish likewise are adversely affected by short wavelengths of light and by ozone.

Dangers of "Attenuated" Living Typhus Vaccine.—Sadusk and Kuhlenbeck give an account of difficulties encountered by Japanese health authorities following the administration of a biliated living murine typhus vaccine. In a group of 290 persons inoculated with this vaccine, 218 (70 per cent) developed symptoms and serologic manifestations of typhus fever. There was 1 fatality. The record of the use of living typhus vaccine presents a series of frank failures. The authors stress the favorable results which have been recently obtained against epidemic typhus by the use of a killed ether extracted yolk sac vaccine.

Anesthesiology, New York

7:477-598 (Sept.) 1946

- Anesthesia in Surgical Treatment of Congenital Pulmonic Stenosis. M. H. Harmel and A. Lamont.—p. 477.
- Pontocaine—Dextrose—Ephedrine for Spinal Anesthesia. J. K. Potter and R. J. Whitacre.—p. 499.
- Effect of Pentothal Alone and in Combination with Oxygen or Nitrous Oxide-Oxygen on Arterial Blood Gases. G. D. Barton, W. R. Wicks and H. M. Livingstone.—p. 505.
- Lethal Hypothermia in Dogs of Various Ages. B. De Boer and H. E. Ederstrom.—p. 518.
- *Use of Curare for Abdominal Surgery in Seriously Injured Patients. E. A. Doud and G. Shortz.—p. 522.
- Question of Cerium Oxalate as Prophylactic Against Postoperative Vomiting. T. Gordh and H. Rydin.—p. 526.
- Stages and Signs of Pentothal Anesthesia: Physiologic Basis. B. Etsten and H. E. Himwich.—p. 536.
- Rotameter in Anesthesia. R. Foregger.—p. 549.
- Regional Anesthesia by Intravenous Route (Slight Modification of Bier's Method). L. Garcia Herreros.—p. 558.

Curare for Abdominal Surgery.—The intravenous administration of curare (intocostrin) was employed by Doud and Shortz as an adjunct to anesthesia in 26 cases of severe abdominal and thoracoabdominal injuries. Ether, with the oroendotracheal absorption technic, and nitrous oxide-oxygen were the agents in all cases. No untoward effects have been observed. Doses of curare sufficiently large to produce respiratory depression or paralysis of short duration did not cause hypotension. Deaths occurring in the series could not be attributed to curare. The surgeons declared that the relaxation was excellent and that the operating time was decreased because manipulation of intraperitoneal contents was easier, exposure readily obtained and closure greatly facilitated. The element of shock present in association with severe abdominal wounds does not appear to contraindicate the use of curare as an anesthesia adjunct.

Methods for Treating Hyperthyroidism —Means believes that the antithyroid drugs such as thiouracil when used in combination with iodine in the preparation of patients with hyperthyroidism for thyroidectomy provide a more complete preparation than has been available heretofore As between treatment of hyperthyroidism by thyroidectomy after preparation with an antithyroid drug in combination with iodine and treatment by prolonged use of an antithyroid drug alone, the author believes that the scales still tip in favor of surgery Treatment with radioactive iodine is an effective way of producing a remission in the thyrotoxicosis of hyperthyroidism, but a final evaluation of how it compares with other modes of treatment must await observation of more cases and over a longer period of time particularly with respect to late untoward side effects, malignancy and renal damage

Immunization Against Influenza — Salk and Francis employed a vaccine which consisted of a suspension of formaldehyde inactivated influenza viruses and contained representative strains of both type A and type B The culture medium for the virus was the chick embryo, and the extraembryonic fluids constituted the immediate source During the epidemic of influenza A that occurred throughout the United States in the winter of 1943-1944, 12,500 students in the specialized training program were involved in studies conducted uniformly but independently by members of the Commission on Influenza in six investigating groups in different parts of the country The estimate that vaccination was 75 per cent effective assumes that the attack rate in the control half of the population under study was not influenced by the presence of vaccinated persons but was the expected rate had vaccination not been done Observations which have a bearing on this point suggest that the assumption may be incorrect The general opinion has been that the duration of the effectiveness of influenza is a matter of weeks or months but the authors think that such statements have been based on questionable evidence or have been made without due consideration of all of the factors involved From recently reported studies evidence is available to support the contention that the duration of effectiveness of influenza vaccination is considerably longer than a few months when vaccine of suitable potency is employed Reactions to influenza vaccine correspond in severity and character to reactions following the administration of typhoid vaccine Although incontrovertible evidence is now available that the resistance of man to infection by the viruses of influenza A and B can be enhanced, it is also evident that the problem of controlling epidemics of influenza by means of immunization cannot be approached only from the point of view of affording individual protection

Intoxication from Massive Doses of Vitamin D — Covey and Whitlock state that vitamin D in massive doses is a powerful and dangerous drug which should be used with caution and that there are definite contraindications to its use It mobilizes calcium from the trabeculae of the bones and thus raises the blood calcium level It often produces cellular degeneration in various organs of the body, and this is most obvious in the kidney The degenerated cells become the repository for calcium The fat tissue of the body is rapidly burned up Nitrogen may accumulate in the blood, presumably because of inability of the damaged kidney to excrete it It is also apparent that mild intoxication with this drug is probably harmless unless it is permitted to continue over a long time and that complete restitution of the injured tissues usually takes place In 4 of the 5 patients observed by the authors ranging in age from 29 to 68 years, vitamin D was taken in dosage larger than is considered safe, namely 150 000 units per day Two of the 5 patients were victims of arteriosclerosis and hypertension, conditions which have been said to contraindicate the use of this drug Two patients increased the dosage voluntarily much beyond the amount ordered by the physician The mental status of the first patient, while not obviously psychotic was known to have deteriorated in comparison with previous observations It is possible that psychic disorders, especially in the aged, should be regarded as a contraindication to the use of this substance in massive dosage The most common symptoms were nausea, vomiting and headache Associated with these symptoms there was a group of findings indicating renal injury The authors conclude that the use of this substance should always be carefully supervised

Methemoglobinemia. Treatment with Ascorbic Acid.— Carnrick and his associates say that in the absence of cardiac or pulmonary disease further study of the blood to establish or exclude the presence of methemoglobin is of considerable importance They recently encountered 2 patients presenting cyanosis as an important symptom In 1 the disease is of unusual interest in that a spontaneous formation of methemoglobin was apparently the cause of the cyanosis In the other patient sodium nitrite therapy was the cause of the cyanosis Methemoglobinemia is commonly accompanied not only with cyanosis but also with disturbances in gastrointestinal function, frequently diarrhea has been noted In 1 of the patients here presented the combination of cyanosis and gastrointestinal symptoms was prominent In both patients methemoglobinemia was suspected and confirmed by laboratory studies Of particular importance in both cases was the striking response of the cyanosis to treatment with ascorbic acid with concomitant alleviation of all clinical symptoms The first patient was given 500 mg of ascorbic acid daily by mouth in divided doses for three days In the second patient 500 mg of ascorbic acid was given intravenously Within four hours there was a noticeable decrease in the amount of cyanosis An additional 500 mg of ascorbic acid was injected intravenously during the remainder of the day in three divided doses Fifty-six hours after the initial therapy the hemoglobin level had fallen from 3 9 Gm to 0 4 Gm per hundred cubic centimeters Treatment of methemoglobinemia has been undertaken in the past by the use of intravenously administered methylthionine chloride but the authors think that ascorbic acid is more desirable for this purpose

Penicillin in Hepatic Syphilis —According to Tucker and Dexter active late syphilis of the liver is a condition rarely demonstrated clinically The initial and essential lesion is the gumma Two methods are available for proving the presence of active hepatic gummas The first and more reliable method is to make a biopsy, a procedure not without risk The second method is to employ a therapeutic test In the 2 cases reported here, penicillin was used The patients received 920,000 and 3 200 000 Oxford units respectively of commercial sodium penicillin intramuscularly, with dramatic alleviation of acute symptoms and sustained objective and subjective improvement over observation periods of six hundred and eighty-six and four hundred and ninety one days These results show that visceral gummas heal under treatment with commercial penicillin mixtures at least as well as they do under other forms of antisyphilitic treatment. The apparently nontoxic properties of penicillin recommend it particularly in cases in which disease of the liver is present. In the second of these 2 cases the diagnosis was substantiated also by biopsy.

Chronic Back Pain and Herniating Intervertebral Disk.—Hyndman presents evidence that degeneration and disintegration of intervertebral disk in the low lumbar region is the predominant cause of chronic pain low in the back. Herniation and rupture of a disk is an advanced stage of degeneration and is associated with the syndrome of compression of a nerve root. The process of degeneration of the nucleus pulposus and annulus fibrosus is a prerequisite to herniation. Whatever role trauma may play, it is only an accessory one. The syndrome of chronic pain low in the back is due to a weakened lumbar or lumbosacral joint. The syndrome of radiating pain in sciatic distribution is due to compression of a nerve root. These two syndromes are separate entities. They are due to different aspects of the same pathologic process and hence may exist independently or combined. Treatment of the degenerating disk consists in removal of the pathologic tissue. The result is contingent on the development of a new fibrocartilaginous disk that serves to fuse the adjacent vertebrae into a mechanical unit. There are a number of different types of herniation.

Role of Tuberculosis Sanatorium in Community. H. F. Schwartz.—p. 447.

***Results of Thoracoplasty.**—This review includes the* patients operated on by Davison at the Chicago Municipal Tuberculosis Sanatorium since 1933. *In all 1,868 operations* were performed on 933 patients. The 933 patients represent 7.2 per cent of admissions. In 54 patients the tuberculosis was moderately advanced and in 879 it was far advanced. There were 57 operative deaths. This represents a mortality of 6.4 per cent. A recent review of 888 cases revealed that 488, or 55 per cent, were apparently arrested. Some were improved and had negative sputum, but others had positive sputum although they were improved. Some were unimproved and had a poor prognosis. The author concludes that the results of thoracoplasty are good when one takes into consideration the advanced stage of tuberculosis at which it is usually performed. Soon there may be a preparation available which will render thoracoplasty less frequently necessary. The most promising at present is streptomycin.

Superior Pulmonary Sulcus Tumor and Pulmonary Tuberculosis.—Bernstein presents the history of a patient with active pulmonary tuberculosis who developed Pancoast's syndrome. This is the second known instance of the concurrence of superior pulmonary sulcus tumor and pulmonary tuberculosis. In the case described by Fried in 1935 the diagnosis of Pancoast's syndrome was suspected clinically and the tumor found at necropsy. Bernstein observed his patient earlier in the course of the disease, established the diagnosis ante mortem, instituted radiation therapy and subsequently confirmed the clinical finding at necropsy. The case is reported because of its rarity and its many interesting aspects. The author concludes that the presence of pulmonary tuberculosis does not preclude the possibility of the development of cancer.

Conjoined Action of Penicillin and Bacteriophages.—Himmelweit, working in the laboratory of Sir Alexander Fleming at St. Mary's Hospital, London, observed that a strain of staphylococcus moderately resistant to both penicillin and bacteriophage became much more susceptible to destruction when exposed to the action of these two biologic agents in combination. Repetition of Himmelweit's experiments in the laboratory of MacNeal and his associates, using their own bacteriophages and cultures obtained from septic patients in their own series, has resulted in confirmation of his observations. Penicillin and the bacteriophages are not antagonistic to each other and in many instances exert a synergistic effect on the bacterial culture in the test tube. This combined action may be designated as a potentiating, conjoined or synergistic effect. This action is also manifest in the clinical use of these agents in treating otherwise malignant infections, particularly those due to staphylococci, colon bacilli and selected members of the streptococcus group. Severe types of infection with staphylococcus, such as chronic osteomyelitis, facial carbuncle and staphylococcic endocarditis, have responded to combined therapeutic use of penicillin and bacteriophages. Intestinal perforation associated with general peritonitis and bacteremia has been successfully treated with coli bacteriophage and penicillin. Bacterial endocarditis due to streptococci relatively resistant to penicillin has responded favorably to treatment with penicillin and suitable streptococcus bacteriophage.

Radical Surgery and Penicillin in Brain Abscess.—LeBeau of the Neurosurgical Clinic of the Faculty of Medicine in Paris thinks that, because of penicillin, more radical operations can be undertaken for abscesses which otherwise could not have been cured. He advocates complete extirpation of the abscess, whether acute or chronic, single or multiple, even though this may mean opening up a communication between the abscess and the ventricle. In three operations before penicillin became available, complete extirpation could not be carried out and there were no survivals. In the next 14 cases (13 with penicillin and 1 without) complete and rapid cure was achieved. Ten of these 14 cases showed a serious form of abscess, including 3 which were metastatic from the lungs. The author has adopted the complete extirpation of the abscess in one stage by employing the method described by Clovis Vincent. He feels that with the use of penicillin brain abscesses should be dealt with like brain tumors.

Cortical Localization by Electroencephalography.—A modified electroencephalographic technic based on the quantitative and statistical analysis of homologous recordings obtained simultaneously has been investigated for its cortical localizing value by Aird and Bowditch. The principle involved is identical with that employed in the neurologic examination in which focal abnormal findings on one side are checked against the normal side as a control. This technic has been employed in 1,200 examinations. Definite cortical localizations were obtained in approximately one third of this abnormal group which gave a high degree of correlation with the clinical findings. Ninety per cent of the remainder had convulsive states or other conditions in which focal signs and symptoms or neurologic findings of localizing value were not obtained. In 248 patients of this group subjected to pneumoencephalography an all over correlation of 81 per cent was observed between the x-ray findings and those of the electroencephalogram obtained by means of the technic of homologous recordings. In 85 proved cortical lesions an electroencephalographic correlation of 95 per cent was obtained. It is estimated that electroencephalographic localization of lesions of a less gross character was made in approximately 20 per cent of the entire group, which correlated well with the clinical and pneumoencephalographic findings and which would not have been detected by other technics. The technic appears to be well justified when used for purposes of localization.

Fluorine Ingestion and Tooth Decay.—Boyd and Cheyne think that certain communities in Iowa provide favorable facilities for the study of the effect of fluorine ingestion on tooth decay, since numerous wells in the state contain notable amounts of fluoride. During the summer of 1944 the authors conducted dental surveys in a region of endemic fluorosis and in three state controlled custodial institutions for children. The population studied was limited to subjects 13 years old or older. The dental findings have been analyzed not only in terms of place of residence and the regional content of fluoride in the domestic water supplies but also on the basis of whether or not mottling of enamel was evident. Dental data have been expressed in terms of the number of surfaces of permanent teeth which have been affected by decay. The data from this study support the thesis that the incidence of dental caries is lessened in areas of endemic fluorosis. The findings differ sharply from several reported studies in their quantitative aspects. The authors found caries of some degree in almost every subject; in many children with mottled enamel and with prolonged fluoride ingestion the incidence of carious tooth surfaces was high. Further, there was no evidence to indicate that the current consumption of water containing submottling amounts of fluoride had lessened the progress of caries in children whose enamel was free from mottling. There is no need to conclude from studies thus far reported that teeth undergo decay primarily because of inadequacy of fluoride ingestion or because of lack of fluorine in the physicochemical structure of the tooth. Fluorinization remains a pharmacologic, not a physiologic, method for the control of caries. These points should be borne in mind in the conduct of fluorine studies. The ultimate answer to caries control probably will lie in the furtherance of innate physiologic protective agencies rather than through pharmacologic procedures.

Wilms's Tumor.—Nesbit and Adams state that the Wilms tumor, adenomyofibrosarcoma or embryonal mixed tumor of the kidney, is the most common renal neoplasm of childhood. Previous reports on this condition give a rather poor prognosis, but half of the patients under review are still living. The 16 patients were treated at the University of Michigan Hospital during the nine year period between 1934 and 1943. Twelve of the patients had nephrectomy and 7 of these are alive three and one-half to eleven and one-half years postoperatively, a survival rate of 58.4 per cent. Two of the nephrectomized patients who had retroperitoneal infiltration with neoplasm and were given postoperative irradiation have survived four and eleven years without clinical evidences of recurrence. One child considered inoperable because of questionable chest metastases was treated by x-rays alone. She has survived ten years and today appears well. The authors believe that among the 8 living patients in the present series 3 owe their survival to irradiation and are therefore led to the conclusion that postoperative irradiation of all patients is indicated.

Immunization Against Whooping Cough. — Lapointe reviews the various types of vaccines that have been employed against whooping cough and says that Strean produced a vaccine which contained 15 billion organisms per cubic centimeter combined with 150 provisional units of pertussis endotoxoid. This combined vaccine has been under clinical trial at La Creche St. Vincent de Paul since 1942. It causes the same local and general reactions encountered with the use of the bacterial type of Sauer. La Creche houses 650 children whose ages range from birth to 4 years. The children are kept in dormitories in groups of 36. The dressing rooms and playrooms are common quarters, so that the children come in close contact. Owing to crowded facilities, isolation is impossible in the event of contagious diseases. Since 1942, 150 children have been vaccinated against whooping cough every year. All received three injections of 2 cc. at one month intervals. Because some of the children were adopted and some died, there remained only 100 vaccinated in a total enrolment of 650 at the onset of an outbreak of whooping cough on July 1, 1945. The immunized children were exposed to pertussis for a longer period than is possible in a family and to much more massive infection. In spite of these unfavorable conditions, not more than 10 per cent of the immunized children contracted pertussis and none had complications or died. Of the 550 controls 450 became ill with whooping cough and 6 developed bronchopneumonia, of whom 3 died, and 2 died of mediastinal emphysema.

Penicillin in Peanut Oil and Beeswax in Endocarditis.—Geiger and Goerner point out that the necessity for prolonged and uninterrupted parenteral treatment in endocarditis has imposed a considerable task on the attendants and has demanded fortitude from the patients, who must either submit to intramuscular injections night and day or tolerate continuous infusion for weeks or months. These difficulties could be eliminated if sustained serum penicillin levels were attainable by the infrequent injection of massive deposits of penicillin in a slowly absorbable form. In 2 cases of subacute bacterial endocarditis due to Streptococcus viridans the authors effected apparent cure with one or two daily injections of massive doses of penicillin in a mixture of peanut oil and beeswax. In another case which had proved refractory to cure after ten months' treatment with water soluble penicillin given parenterally an afebrile and asymptomatic state with sterility of the blood was maintained with a single daily injection of penicillin in oil and beeswax. Positive blood cultures, however, were obtained whenever this treatment was discontinued. It is believed that this patient can be kept indefinitely in remission by this simple treatment. Satisfactory serum penicillin concentrations were present for twelve hours and often for twenty-four hours following a single injection of 300,000 to 600,000 units of penicillin in oil and beeswax.

Pulmonary Tuberculosis in Medical Students.—Brean and Kane assert that tuberculous infection of the lung remains the most serious medical problem that confronts the medical student. They review the material on pulmonary tuberculosis that has accumulated in the records of the health office at Harvard Medical School during the last twenty-three years. The incidence of significant active adult type pulmonary tuberculosis was 2.2 per cent. Although the number of cases of pulmonary tuberculosis discovered in the last two years of the medical school course was four times as great as the number developing in the first two years, the incidence of acquisition of tuberculous infection was about the same (12 or 13 per cent annually) for each academic year. This constant annual attack rate suggests that factors other than opportunity for infection are responsible for the fourfold increase in cases of pulmonary tuberculosis during the term of clinical training. The duration of disability caused by the pulmonary lesion was closely correlated with the severity of the lesion at the time of its discovery. Lesions detected by the appearance of symptoms were of greater severity and carried a far greater period of disability than those discovered by routine methods. The adoption of a program in which surveys are made at intervals more frequent than once a year led to the elimination of almost all symptom detected cases and of all major lesions. It is the belief of the authors that a semiannual examination represents the maximum interval for routine reexamination by x-ray or by tuberculin tests not only for medical students but also for nurses and interns.

Streptomycin in Tularemic Pneumonia.—Peterson and Parker report that a man aged 29, who was an employee of the Rocky Mountain Laboratory, became suddenly ill on Feb. 23, 1946 with a chill followed by fever, sweating and headache. Cough and pleuritic pain appeared on the fourth day. On March 1 the patient was hospitalized. X-ray examination of the chest showed diffuse infiltration of the lower lobe of the left lung. Fifty thousand units of penicillin was given intramuscularly, followed by 25,000 units every three hours, but the course remained febrile. On March 6 the diagnosis of tularemic pneumonia was established by laboratory tests. Penicillin was discontinued and streptomycin hydrochloride was administered intramuscularly, 50,000 units every three hours for eighteen doses. This exhausted the available supply. Three days later a supply of streptomycin sulfate was received. On March 11 streptomycin therapy was resumed. The patient was able to sit up on March 12 and was discharged from the hospital on March 15. The patient received 0.9 million units during the first course of treatment and 1 million during the second course, a total of 1.9 million units of streptomycin. It is doubtful whether the second series was necessary. The patient had been afebrile for three days when the second course was started.

Heparin and Papaverine in Treatment of Gangrene.—McLean and Johnson report the history of a man aged 44 who developed gangrene in the foot following trauma, including tibial fracture and an accidental cut into the anterior lower part of the leg. As a result of inadequate supply of blood to the foot, signs of beginning gangrene appeared. It was decided to try to improve the circulation by the use of heparin, papaverine hydrochloride and the principle of intermittent venous occlusion. Heparin was used to increase the fluidity of the blood. The papaverine was used for its effect in relaxing striated muscle of vessels. The apparatus for producing intermittent venous occlusion was operated for forty-five minutes every four hours for sixteen days. The triple treatment was begun five days and seven hours after the injury. At this time it appeared that amputation might be necessary eventually. The final tissue loss was small portions of the ends of the toes and all of the nails. Amputation was avoided and a satisfactory functioning foot obtained. Recovery usually is not expected after forty-eight hours' lack of blood.

Chemical Production of Prolonged Sympathetic Paralysis in Causalgia.—Rasmussen and Alessi say that the availability of a slowly absorbed local anesthetic agent (rectocaine) suggested the possibility of increasing the effectiveness of paravertebral injections in the treatment of causalgia by prolonging the resultant sympathetic paralysis. Rectocaine contains 5 per cent benzyl alcohol, propylaminobenzoate and procaine. The first patient had causalgia of the left arm. A paravertebral injection was done. Fifteen cc. of 2 per cent procaine was injected along the left side of the bodies of the first and second thoracic vertebrae, producing vasodilatation of the hand and typical Horner's syndrome within five minutes. The pain was relieved for one hour and then returned. Four days later the paravertebral injection was repeated. Before the needles were withdrawn, 2.5 cc. of rectocaine was injected into each. The sympathetic paralysis and relief of pain persisted for forty-eight hours, with the latter then returning. Since it was felt that the amount of rectocaine was insufficient a third injection was done. After 5 cc. of procaine injected at each segment had again produced prompt sympathetic paralysis and relief of pain, 4 cc. of rectocaine was introduced into each of the two needles. This time the pain did not return, and the relief persisted throughout the follow-up period of ten weeks. A second patient with causalgia was treated in a similar manner and relief was obtained

Homologous Serum Jaundice.—Spurling and her associates made a follow-up study of 2,040 patients transfused with pooled serum and/or plasma, of 1,284 patients transfused with whole blood only and of 1,284 control patients not transfused. The incidence of jaundice in the patients receiving pooled plasma or serum was 7.3 per cent. Frank homologous serum jaundice did not develop in any patient receiving whole blood. Jaundice did not develop among the controls within five months of transfusion. The character of the jaundice was with one exception mild. The symptomatology and incubation period were in accord with previous accounts. To minimize the risk of homologous serum jaundice after transfusion, (1) human serum for prophylactic purposes should not be pooled, (2) for transfusion purposes only small pools should be used, (3) all blood products issued should carry an identification number, (4) records should be kept of the number of the bottle given to a particular patient and (5) machinery should be maintained for the notification of jaundice following transfusion, thus enabling the withdrawal of icterogenic material from circulation.

Riboflavin Deficiency.—Gopalan found that genital symptoms of riboflavin deficiency occur chiefly during the childbearing age. Of 67 females who presented genital symptoms in association with other signs of riboflavin deficiency and in whom these symptoms cleared on the administration of riboflavin, 64 were adult women and 3 were children. The minimal genital manifestation of riboflavin deficiency in women is an increase in the normal vaginal secretion. The resulting leukorrhea is apparently the result of increased transudation through the vaginal walls. Pruritus vulvae is present in cases of profuse leukorrhea. The leukorrhea abates on treatment with riboflavin, and the pruritus and vulvitis also subside. Pruritus ani, perianal inflammation and anal fissure are among the signs of riboflavin deficiency. Treatment with 10 mg. of riboflavin daily by mouth for two to four weeks leads to rapid healing of the fissure and subsidence of other signs. Scaly dermatitis of the scrotum is frequent in subjects with riboflavin deficiency, but preputial ulceration is also observed. Both these conditions are seen much more often in men than in boys. Among 92 cases of riboflavin deficiency in men above 18 years, 59 showed scrotal dermatitis which was associated with ulceration of the preputial margin in 32 cases; 3 cases showed preputial ulceration without scrotal involvement. In several cases of riboflavin deficiency observed by the author, the angles of the lids showed ulceration. He designates this condition as angular blepharitis.

Bubonic Plague.—Simeons and Chhatre say that 1,039 persons with plague were admitted to an Emergency Plague Hospital from the end of July 1945 to the middle of January 1946. There were 19 with nonbubonic plague, all of whom died. Of the remaining 1,020 patients 20 were treated by various methods and with apparently insufficient sulfonamide doses before a fixed routine was established. There remained 1,000 consecutive patients with bubonic plague who received a carefully supervised treatment with sulfathiazole or sulfadiazine. Sulfathiazole was injected intramuscularly and sulfadiazine intravenously. When sulfathiazole was injected, sulfathiazole tablets were given by mouth; when sulfadiazine was injected, only sulfadiazine tablets were given in addition. Two injections (1 Gm. each in adults) were given daily and two tablets four hourly day and night. This was continued until the temperature stayed below 100 F. for at least eight hours; from then on only tablets were continued. Some patients had as many as nineteen injections. Liberal use was made of dextrose-saline infusions, nikethamide, digilanid, vitamin C, bromide and morphine. Attention was paid to an adequate fluid intake. Early treatment seems to be important. The mortality rate among patients treated within the first twenty-four hours is 6.61 per cent, whereas after twenty-four hours it rises to 19.67 per cent. In 1,000 patients the mortality was 18 per cent; excluding moribund patients the mortality was 8.48 per cent.

Disseminated Encephalomyelitis and Multiple Sclerosis.—Margulis and his co-workers isolated two strains of filtrable virus—from the blood of 1 patient and from the cerebral tissue of another with acute disseminated encephalomyelitis. These strains have proved to be identical and to differ from other known human neurotropic viruses. The syndrome of acute disseminated encephalomyelitis has been produced in animals by means of inoculation with this virus. The morphologic picture obtained has proved identical, particularly in rabbits and puppies, to that found in man with acute disseminated encephalomyelitis. An attempt has been made to neutralize the virus thus isolated with the serums of patients suffering from acute disseminated encephalomyelitis and multiple sclerosis. The virus has been neutralized by serums from 50 per cent of patients with multiple sclerosis and from 70 per cent of patients with disseminated encephalomyelitis. These positive neutralization tests suggest that acute disseminated encephalomyelitis and multiple sclerosis have the same cause in some patients, while in others the same anatomic and clinical syndromes may be elicited by other agents or possibly by the same agent but with a different antigenic structure. Specific vaccine therapy has yielded satisfactory results in a small number of patients with acute disseminated encephalomyelitis and multiple sclerosis. There has been clinical improvement with considerable increase of antibodies in the blood.

Penicillin and Sulfathiazole for Typhoid Carriers.—Comerford and his associates employed both sulfathiazole and penicillin on 2 established carriers, both of whom regularly excreted Bacterium typhosum phage type D_1 in their feces, 1 of them even after cholecystectomy. An initial dose of 2 Gm. of sulfathiazole by mouth was followed by 1 Gm. at four hour intervals. Approximately 500,000 units of penicillin dissolved in 10 cc. of sterile water was given intramuscularly at the same time. The treatment was continued for eight and seven days respectively, the total doses of penicillin amounting to over 24 million and 21 million units. Bacteriologic examination of every stool after treatment failed to reveal the presence of Bact. typhosum in them for periods of over one hundred and thirty days in the 1 case and over one hundred and sixteen in the other. Two months after treatment both patients showed reduced agglutination titers to typhoid-Vi antigen.

Pyridoxine in Epilepsy.—Since it had been observed that pigs and rats deprived of pyridoxine developed typical epileptic fits, Fox and Tullidge decided to try medication with pyridoxine on 8 epileptic school boys, who were selected because of the regularity of their fits. Doses of 20 mg. or 100 mg. each day were tried for weeks, but there was no evidence of a decrease in fits in any of the patients. The authors conclude that it is unlikely that pyridoxine would be of value in epilepsy.

Painful Feet in Prisoners of War in the Far East.—According to Cruickshank the symptom known as painful feet, burning feet or happy feet appeared among prisoners of war in Changi Camp, Singapore, at the end of July 1942, five and a half months after capture. This report is based on 500 personally observed cases. A dull ache was usually the earliest abnormality and was felt below the heads of the metatarsals and in the balls of the toes. At first it was present only at night after a long day's standing or walking. Later the ache became more pronounced, coming on in the early morning and increasing when the patient retired to bed. Sharp stabbing pains became superimposed on the ache in 58.6 per cent of the 500 cases. A single pain lasted from half a second to two seconds, shooting, parallel to the toes and soles of the feet, into the heels, through the ankle joints and sometimes up the shins to the knees. In 6.4 per cent there were similar symptoms in the hands, but these usually developed only in long-standing cases four to eight weeks after the onset of symptoms in the feet. The symptom developed when the diet of the prisoners was deficient in protein and the vitamin B complex. Hypertension and exaggerated tendon reflexes were added features in some cases. The diet records and the beneficial effect of treatment with nikethamide (the diethylamide of nicotinic acid) point to a deficiency of nicotinic acid, perhaps in conjunction with riboflavin deficiency, as a major factor in the production of the syndrome.

Folic Acid in Treatment of Megaloblastic Anemia.—Davidson and Girdwood employed folic acid in the treatment of 9 patients with megaloblastic anemia. Of the 6 patients with addisonian pernicious anemia 4 were treated with folic acid daily by mouth in doses ranging from 5 to 20 mg.; 2 received a single large dose by the parenteral and oral route respectively. Of the patients receiving daily oral treatment, only the 1 who received 20 mg. daily had a reticulocyte response and red cell rise completely up to the standard demanded by the U. S. P. board. Two others, who received 10 mg. daily by mouth, showed suboptimal rises in reticulocytes. The patient who received 5 mg. daily had a rise in erythrocytes that conformed to the U. S. P. standard, but the reticulocyte rise was suboptimal. In all 6 cases the bone marrow was transformed from a megaloblastic to a normoblastic state. The clinical state of the patients improved coincidentally with the blood. A patient who was given 200 mg. of folic acid intramuscularly in the first day of treatment showed a sharp rise of reticulocytes and an increase of more than 1 million red cells and 20 per cent hemoglobin in eleven days. In the sixth patient an excellent response resulted from a single dose of 400 mg. orally. If such a response can be obtained regularly, the simplest and most effective method of treatment may prove to be an initial large dose followed at weekly or fortnightly intervals by doses of 50 to 100 mg. Three patients with megaloblastic anemia which had been refractory to "anahaemin" responded to folic acid, which was, however, unable to restore the blood to normal. Since 2 of these patients had previously responded to proteolyzed liver, it is suggested that folic acid might be the active principle of proteolized liver.

Gamma Globulin in Prophylaxis of Measles.—Anderson and Ket report that during an epidemic of measles in Melbourne 116 children who were closely exposed to infection were given gamma globulin prophylactically. About half of the children received 0.1 cc. of gamma globulin per pound of body weight; most of the others received 0.025 cc. per pound of weight. Sixty-seven of the children did not develop measles, 46 had a modified attack and in 3 the course of the disease was apparently uninfluenced by globulin. Of those who had received the larger dose, more than three fourths remained free from measles, whereas of those receiving the smaller dose more than half developed a modified attack but there were no complications. The 3 patients in whom the course of the disease was apparently uninfluenced had received the smallest prophylactic dose.

Cooley's Anemia.—Fawdry says that the laboratory test which most strikingly shows the presence of Cooley's anemia is the plotting of the fragility curve. The harboring of the trait is of no consequence to the individual, though it may be to his offspring, so he usually survives unrecognized to adult age. The author reports 6 cases that represent the intermediate group which reaches and passes puberty but yet may be seriously incapacitated. All 6 patients showed splenomegaly, hypochromic erythrocytes and increased resistance of the cells to hemolysis by hypotonic saline solution. One patient showed a great increase of normoblasts in the marrow. Two were typical of the mildest degree of the affliction: the first had no symptoms directly referable to his blood dyscrasia and the second only the icterus of the conjunctivas and a large spleen. As they do not have anemia, there has been no interference with their physical capabilities. Except possibly for lifelong repeated transfusions, which is scarcely practicable in Cyprus, there is as yet no therapy whereby the anemic patient can be restored to health and usefulness in the community. The milder form of the disorder is fairly frequent throughout the island.

Vitamin K and Biliary Tract Surgery.—Mallet-Guy and his associates employed prophylactic vitamin K treatment in 225 cases of biliary tract surgery. Only 63 patients had a normal prothrombin level, while 162 patients had a prothrombin deficiency. Preoperative determination of the prothrombin level is advisable in all cases of chronic icterus and in cases with a history of jaundice or of previous involvement of the common bile duct in the absence of chronic icterus. There was not a single death from a postoperative hemorrhage in a three year period during which biliary tract patients with hemorrhagic diathesis were treated with oral administration of 200,000 international units for twenty-four hours combined with a subcutaneous injection of 10 mg. of vitamin K when the prothrombin deficiency amounted to 20 per cent of the normal level or where the urgency of the surgical intervention required a rapid improvement of the prothrombin level. This treatment should be continued for two to three days prior to intervention. In cases in which the prothrombin level oscillates around 75 per cent of the normal, 150,000 units should be given by mouth for four to six days. In cases of icterus this treatment should be combined with oral administration of 1 Gm. of biliary extract for every 150,000 vitamin K units. Continuation of the satisfactory effect is ensured by a maintenance treatment with a twenty-four hour dose of 100,000 to 150,000 units for several days after the intervention.

Gangrene of Venous Origin.—Fontaine and Forster report 2 cases of venous gangrene. A man aged 40 presented a thrombophlebitis of both lower extremities after a hemorrhoidectomy. After several weeks extensive skin gangrene involving the anterior aspect of the right leg and foot had separated, and grafting of the granulating surface of the wound became possible. Mummification of four toes of the left foot occurred. Residual edema and loss of the toes was a much better result than could have been expected. It shows that venous gangrene, although associated with a massive slough, may be limited to the skin. A boy aged 8 years fell on his arm, an erroneous diagnosis of fracture of the elbow was made and a plaster cast was applied. Moist gangrene of the hand and the inferior third of the left forearm occurred within a few days. X-ray examination revealed the absence of any fracture. Amputation became imperative because of the severe massive gangrene. Microscopic examination of the amputated extremity showed thrombosis of all the veins, while the arteries were normal. Rich collateral venous circulation is responsible for the fact that venous gangrene occurs only after extensive obliteration of the veins. Poor general condition or associated arterial spasm can favor the occurrence of venous gangrene but is not indispensable to it. Anoxemia resulting from venous stasis due to deficient collateral circulation is responsible for the occurrence of venous gangrene.

*Therapeutic Value of Procaine Hydrochloride Infiltration of Lumbar Sympathetic Ganglions in Arteritis. P. Wertheimer, P. Frieh and R. Gautier.—p. 319.

Procaine Infiltration of Lumbar Sympathetic Ganglions in Arteritis.—Wertheimer and his associates infiltrated the lumbar sympathetic ganglions with procaine hydrochloride as the only method of treatment in 38 cases of arteritis with calcareous infiltration in persons whose average age was 65 years. Ischemic gangrene supervened in 12 of the cases. Good results were obtained in 22 cases, stabilization took place in 4 cases, amputation was performed in 8 cases and death occurred in 4 cases. Good results were obtained in 7 of the cases with gangrene, rapid death occurred in 2 and amputation became imperative in 3, with death in 1 of them. The periods of observation varied from six to nine years in 10 cases, from three to four years in 4 cases and from one to two years in 11 cases. Amputation need not be considered as absolute failure of treatment, since in 3 cases a temporary improvement lasting for six months to three years was obtained prior to amputation. In the majority of the cases repeated infiltrations of lumbar sympathetic ganglions were required. The good results, particularly those in cases of gangrene, suggest that in the long run repeated procaine hydrochloride infiltrations of lumbar sympathetic ganglions may have the same effect as sympathectomy, but this hypothesis requires further control.

Dermoid Cyst with Cancerous Degeneration of Thyroid Tissue. J. H. Müller.—p. 330.

Necrosis of Renal Cortex and of Anterior Pituitary During Pregnancy.—Hügin reviews the histories of 2 pregnant women who developed severe eclampsia with anuria and intrauterine death of the fetus. Both women died and necropsy revealed the hitherto unknown combination of necrosis of the renal cortex and of the anterior lobe of the hypophysis. The microscopic changes are described and evaluated. These changes and reports in the literature indicate that the disorder in question represents a toxic disturbance of pregnancy in which there may occur severe changes in the tubular and vascular portions of the kidney, with total infarction of the renal cortex and necrosis of the anterior pituitary, and both organs usually show extensive vascular thrombosis. The tissue changes are mainly degenerative in nature; inflammatory changes occur less frequently.

Mucin Splitting Ferment in Human Sperm.—Eichenberger studied 76 sperm specimens from 53 men, the majority of whom had proved sterile over more than two years of marriage and requested examination on this account. The author found in normal human semen a ferment having qualities identical with those of hyaluronidase. There is usually a parallelism between the number of spermatozoa and the hyaluronidase contents of the sperm. Semen which does not contain spermatozoa shows no hyaluronidase activity. Spermatogenesis and production of hyaluronidase must be considered as two processes which condition each other reciprocally and are inseparable. The fermentative insemination theory explains the rapid decrease of fertility in males whose semen contains less than 60 million spermatozoa per cubic centimeter of semen.

Clinical Features of Tuberculosis in Children J Rutishauser Scharpf —p 134
Pseudolithiasic Type of Tuberculosis of Kidneys (Tuffier) R Allemann —p 149

Besnier-Boeck-Schaumann Disease—Leitner reports 8 cases of Boeck's disease in 5 male patients between the ages of 9 and 54 years and in 3 women between the ages of 25 and 43 years The tuberculous etiology of Boeck's disease is strongly suggested by the transition from benign granulomatosis to tuberculosis in 3 of these cases, by the simultaneous occurrence of osteitis tuberculosa multiplex cystoides and of tuberculosis in the bones in 1 case, and by the tuberculin test changing from negative to positive in 4 cases The similarity of the clinical symptoms and of the course of benign granulomatosis in a brother and sister suggests that the constitution plays an important part in the course of Boeck's disease The tuberculin test was slightly positive in the sister and negative in the brother In 1 case benign granulomatosis occurred after a primary infection The microscopic picture of this case with its small caseous masses suggests that the transition from the allergic condition of the primary infection to that of the benign granulomatosis was not yet terminated and that the caseous masses depended on the allergy which preceded Boeck's disease The concept of Boeck's disease as a specific type of tuberculosis explains the fatal course in 2 of the author's cases The tuberculin reaction is to be considered as an antigen antibody reaction The negative tuberculin test in benign granulomatosis may be the result of the fixation of the antibodies at the site of their production (the reticuloendothelial system) by the antigens of the Koch bacillus which are destroyed at the same site The reticuloendothelial system is to be considered as the central factor in the defense mechanism, an immunity such as can be produced in animals or human subjects by desensitization, but not an anergy, may be observed in benign granulomatosis with its productive reticuloendothelial system reaction A real anergy may be observed in acute tuberculous septicemia characterized by nonspecific necrosis, abundant bacilli and a very rapid malignant course The absence of tissue defense in the reticuloendothelial system may be responsible for the negative tuberculin test Benign granulomatosis differs from generalized caseous tuberculosis of the lymphatic system, which in spite of the same localization is characterized by a generalized and uniform caseous process and by its malignant course

Methyl Testosterone and Addison's Disease—In studying the action of testosterone on uterine fibromyoma Atria and his co workers found that the subcutaneous implantation of tablets of methyl testosterone exerted a noticeable influence on the pulse and the arterial pressure whereas testosterone propionate did not have the same effect Because of this observation the authors decided to try implantation of methyl testosterone in cases of adrenal insufficiency In a man aged 37 and a woman aged 40 subcutaneous implantation of methyl testosterone corrected the subjective disturbances and the main clinical signs of chronic adrenal insufficiency In the first patient 120 mg of methyl testosterone was implanted into the gluteal region and in the second patient 100 mg Seventy days after the implantation the first patient was still in a favorable condition The authors stress the prolonged effect in relation to the low dose The low dosage has the advantage that it eliminates the excessive dosage of desoxycorticosterone and the masculinization in female patients

Case of Mastoiditis Causing Recurrent Pneumonia and Dyspepsia with Atrophy in Infant P Krepler —p 291

Gonadotropic Neurosecretion — Increasing amounts of anterior lobe of the pituitary, of diencephalon and of uncus substance of dogs were implanted into infantile albino rats by Richter and Schuler Occasionally guinea pigs and rats were used as donors In addition to the microscopic criteria of the gonadotropic effect of these substances on the infantile rat ovary the weight of the ovaries and uteri of the animals experimented on was ascertained, adding an objective measure of the intensity of the gonadotropic reaction elicited by the implantation The increase in weight of the ovaries and of the uteri paralleled the weight of the implanted amount of the anterior pituitary lobe substance The weight of the ovaries and of the uteri of the rats varied between the upper and lower normal limit when increased amounts of diencephalon and uncus substance were implanted A gonadotropic reaction thus resulted only from the anterior pituitary lobe implants and not from those of the diencephalon or uncus substances The tuber cinereum, therefore, cannot be considered as the site of production of gonadotropic hormones Destruction of the gonads and disturbances of the sexual impulses resulting from electrocoagulation of the tuber cinereum suggest that the tractus supraopticohypophyseos but not a "nervous center' has been destroyed The tractus supraopticohypophyseos is to be considered the route by which the nervous impulses which are continuously needed for its support and regulation are conveyed to the pituitary It may be that the chemical process occurring in the terminal branches of the tractus supraopticohypophyseos is similar to that which occurs in the transmission of stimuli to vegetative and motor nerves

Eupaverin in Arterial Embolism—A case of bilateral embolism of the axillary artery in an adipose woman aged 77 is reported by Bruckschwaiger The emboli were removed under local anesthesia and the arteries were sutured Immediately afterward a narrowing of the vessels was observed at the suture site and peripherally, the vessels were pulseless An injection of 0 06 Gm of methylene dioxy benzyl methyl-methylene dioxyisoquinoline (eupaverin) in 2 cc was made into the artery above the suture site The width of the artery was restored to normal within a few seconds and the pulse in the radial artery became definitely palpable The patient complained about unpleasant formication and "awakening' of the hand The livid color of the skin turned to a healthy red The extremity became warm and sensory perception was restored Normal function of both upper extremities resulted four weeks after the surgical intervention Early surgical treatment of arterial embolism combined with administration of eupaverin may prevent failure of embolectomy, while conservative treatment of embolism of the iliac femoral and axillary arteries with eupaverin may be harmful The spasmolytic effect of the drug may cause the embolus to migrate to another site where its surgical removal would be more difficult Consultation of the internist with the surgeon prior to the administration of eupaverin is *imperative* in all cases of arterial embolism and particularly in circulatory disturbances of the extremities associated with typhus

Nontropical Sprue Combined with Addison's Disease.—A man aged 52 complained of loss of weight, fatigue, painful tongue, dry mouth and thin foamy stools of light color The sense of smell was reduced and coughing brought up mucus The hands and feet were cold and the feet were swollen Years before the patient had had joint disorders and had been treated with gold preparations After that symptoms appeared which were similar to those he had now In the differential diagnosis the disease of Besnier-Boeck and tuberculosis were considered but ruled out Many symptoms indicated nontropical sprue, but there were also some, particularly the diffuse pigmentation of the skin and mucous membranes and hypotension, which suggested Addison s disease A combination of these two diseases was accepted While it has been established that Addison's disease is the result of a disorder of the adrenal cortex, it has been suggested by Verzar that this is true also of nontropical sprue As a corroboration of this opinion de Groot found that many symptoms of sprue improved noticeably under treatment with a preparation of the adrenal cortex

Copper in Treatment of Bronchial Asthma—Klaarenbeek obtained favorable results with a copper preparation in patients with bronchial asthma Best results were obtained in patients up to 20 years of age He reports 7 additional cases of bronchial asthma in which the copper preparation was used All of these patients were less than 26 years of age The copper preparation had been used by others in polyarthritis and certain forms of tuberculosis It produces favorable results in young asthma patients The dosage must be adjusted for the individual patients According to the usual scheme two injections of 10 and 25 mg respectively are given during the first week One injection of 50 mg is given weekly during the following four weeks If the attacks cease, 100 mg can be given every other week, but if this is not the case 100 mg or more should be given every week until the attacks stop The effective dose can be given for four weeks, and after that the aim should be to prolong the interval by one week after four injections One or two injections per month will usually suffice

Blood Pressure During Starvation and Recovery.—During the period of starvation, when loss of weight was observed in the majority of persons, Lups and Francke studied the relationship between the state of nutrition and the behavior of the blood pressure They found that in April 1945, during the period of severest hunger, the systolic as well as the diastolic blood pressures were definitely lowered In September 1945, when 80 per cent of the people examined had increased in weight considerably, the blood pressure had increased in 77 per cent of those with hypotension in 47 per cent of those with normal pressure and in 25 per cent of those with hypertension The authors think that the low rations particularly the shortage of proteins, were responsible for the lowering of the blood pressure readings

Treatment of Acute Bacillary Dysentery.—The observations reported by Molenkamp were made in a Japanese internment camp He describes the pathologic changes taking place in the intestine, differentiating 3 stages (1) the catarrhal stage, (2) the stage of crust formation and (3) the stage of cicatrization In the treatment, rest is of great importance for the intestine Dietetic measures were employed and in addition the combined administration of sulfaguanidine (5 times 1 5 Gm) and tincture of opium (5 times 15 drops) for five days When the patient suffered from constipation the opium was omitted When necessary this treatment was repeated after several days The treatment proved effective in acute, mild and moderately severe cases

*Insulin Therapy of Ulcerative Disease M A Yasinovskiy —p 310
*Question of Formation of Renal Stones After Injury to Long Bones A P Tsulukidze —p 343

Insulin Therapy of Ulcerative Disease.—In treating 98 patients with gastroduodenal ulcer, Yasinovskiy administered insulin to 98, insulin and atropine to 69 and atropine alone to 37 Patients in the insulin group received 10 units of insulin twice daily, before breakfast and before dinner All the patients received the usual bland ulcer diet plus 50 Gm of sugar daily The diet was adequate in calories and vitamins Significant improvement was noted in 85 of the insulin group of 98, in 9 very little change was noted and in 4 there was exacerbation of the symptoms Improvement therefore took place in 86 7 per cent Of the 37 patients treated with atropine 35 showed definite improvement In the group receiving combined insulin-atropine treatment, considerable improvement was accomplished in practically all cases The duration of improvement in the insulin group lasted from three to twelve months As a rule recurrence was brought about by dietetic errors The insulin treated group and the atropine treated group presented a striking difference in the acidity of the gastric contents The atropine group contained 60 per cent of patients with hyperacidity at the beginning of the treatment On the completion of the treatment the group did not contain any instance of hyperacidity In the insulin treated group the number of cases with hyperacidity not only did not diminish but increased from 47 per cent to 50 per cent The group of patients treated with insulin and atropine occupied a median position with the number of cases with hyperacidity reduced from 64 per cent to 28 per cent The results obtained with insulin therapy of ulcerative disease suggest that there is no definite parallelism between the clinical course of peptic ulcer and acidity of the gastric contents The effect of insulin cannot be explained alone by its action as an alkalizing factor and by its action on the vegetative nervous system The author believes that its effect is also due to its action on a functionally inadequate liver and pancreas Insulin therapy of ulcer is particularly indicated in cases of hypochlorhydria in the presence of advanced emaciation associated with involvement of the pancreas and the liver

Renal Stones After Long Bone Injury.—Tsulukidze states that, of 45 combat men admitted to his clinic because of renal stones, 8 gave a history of gunshot wounds Four of these had gunshot wounds of the thigh and leg Analysis of 184 postmortems of men with trauma of the bones of the lower extremity revealed the presence of renal stones in 5, 4 sustained a fracture of the thigh and 1 a gunshot fracture of both legs Pathologists not infrequently record the presence of sand in the kidneys in subjects with bone injury, particularly of bones of the lower extremity The role of bone injury in the formation of renal stones, according to a majority of authors, is due to an increase in the blood calcium and to infection The author believes that fat embolism associated with fractures is another factor Among other conditions favoring renal calculosis is the passive state of the patient and the diet The passive state of the patient favors alteration in the blood circulation in the kidney and urinary stasis Fat embolus lodged in the kidney can constitute an organic nucleus for deposition of salts The fat embolism may also produce an infarct which will act as a nucleus for a stone A septic embolus may be transferred to the kidney when a fracture of the bones of the lower extremity is complicated by thrombophlebitis

Book Notices

Surgical Treatment of the Nervous System. Supervising Editor: Frederic W. Bancroft, A.B., M.D., F.A.C.S., Associate Clinical Professor of Surgery, Columbia University, New York. Associate Editor: Cobb Pilcher, M.D., F.A.C.S., Associate Professor of Surgery, Vanderbilt University School of Medicine, Nashville, Tennessee. Cranial and Intracranial Surgery, Tumors, Epilepsy and Cranial Nerve Disorders, Spinal Cord, Autonomic Nervous System, Peripheral Nerves. Fabrikoid. Price, $18. Pp. 534, with 298 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1946.

The editors of this excellent textbook have organized the efforts of neurosurgical authorities from various centers in the United States. The result is an exceedingly useful volume dealing with the many and highly diversified problems of surgery of the brain, the spinal cord and the peripheral and autonomic nervous systems. Each author presents all the known facts relating to the pathology, diagnosis and treatment of his subject. The chapters are interestingly written and easily assimilated, especially since there is little similarity between the literary styles of the various contributors. In the words of the editors, "a healthy diversification of opinion on neurosurgical problems as a whole" is obvious and is gratifying to the critical reader. The entire field of clinical neurologic surgery is covered in this fine work, including a chapter on chemotherapy. In the rapidly growing field of neurologic surgery there has been an urgent need for a thorough and authoritative textbook covering all the problems encountered in this specialty. Several previous textbooks have been excellent but are now outdistanced by the rapid developments in neurosurgery stimulated by the war. This single volume presents a comprehensive, authoritative and modern view of clinical neurosurgery. It should be a standard textbook for medical students and deserves to be read by every neurologic surgeon and by every other surgeon whose endeavors bring him into contact with the central, peripheral or autonomic nervous system.

Environmental Warmth and Its Measurement: A Book of Reference Prepared for the Royal Naval Personnel Research Committee of the Medical Research Council. By T. Bedford. Medical Research Council, War Memorandum No. 17. Paper. Price, 9d., 25 cents; Including Supplement, 2s. 3d., 45 cents. Pp. 40, with 10 illustrations. London: His Majesty's Stationery Office, 1946.

This small and timely booklet sets forth in nontechnical language descriptions of the various instruments used in measuring environmental warmth—both radiant and kinetic—and the methods of evaluating the significance of their readings. The recent years of prolonged naval action in tropical waters brought a keen appreciation of the debilitating and efficiency lowering effects of hot environments on exposed personnel. Radiant and so-called wild heat became very important in combat vessels during periods of action or alert, presenting acute problems in personnel welfare and efficiency. Recognition of these problems and the need for their solution led to the preparation of this booklet as a first step in the collection of needed facts. The U. S. Navy already is air conditioning its newly constructed combat ships, and the beneficial results in improved health and efficiency of the ships' personnel are already obvious. Since workers in the medical sciences rarely have a clear appreciation of what radiant heat means in man's heat loss problem, this booklet is heartily to be recommended for their perusal. It is intended primarily as a working guide for those directly engaged in solving the Royal Navy's heat problems aboard ship.

Les tumeurs et les polypes du cœur: Etude anatomo-clinique. Par le D^{r} Ivan Mahaim. Préface du Professeur Dr. Jean-Louis Nicod. Monographie de l'Institut d'anatomie pathologique de l'Université de Lausanne. Paper. Pp. 568, with 67 illustrations. Paris: Masson & C^{ie}; Lausanne: F. Roth & C^{ie}, 1945.

The various tumors of the heart and their clinical manifestations are described. The book is divided into sections according to the location of the tumors. Thus, two hundred pages are devoted to "polyps" of the heart. Polyps are defined as tumors bulging into cardiac chambers, be they rhabdomyomas, lipomas, fibromas, myxomas or myxomatous thrombi. A serious criticism of the terminology of this book is that the differentiation between organized thrombi and myxomas is not clear: thus, a number of the tumors described are mural thrombi. Another unfortunate feature of the book is the lack of microscopic studies in some important cases.

Numerous observations illustrate the symptomatology and the various mechanical accidents caused by these "polyps." The accidents are classified into three types: (*a*) arterial embolism, (*b*) obliteration of a cardiac chamber, (*c*) occlusion of a cardiac orifice (tricuspid, mitral). Illustrating the first type, a case with embolism into the middle cerebral arteries is reported. The emboli were composed of "myxomatous appearing" connective tissue rich in blood vessels and histiocytes loaded with hemosiderin. The original "polyp" was found in the right auricle and was not examined microscopically but was classified, nevertheless, as a "myxomatous polyp." Emphasis is placed on the microscopic examination of the emboli because they represent biopsies of "cardiac polyps." Cardiac polyps are not inaccessible to surgery when they are benign. In some cases the "polyps" were primary spindle cell sarcomas or metastases from primary carcinomas of the kidneys or of the organs of reproduction.

In the second part of the book are described the benign "nonpolypoid" tumors of the heart. The hemangioblastoma and the benign mesothelioma belong to this group. The benign mesothelioma is a rare tumor, usually located in the septum near the Tawara node. It is believed to arise from epicardial inclusions in the septum. The symptomatology of this tumor is illustrated by carefully studied cases.

The malignant tumors of the myocardium are considered in the third part. They are classified as primary and secondary. Numerous histologic varieties of primary sarcoma of the myocardium are described. The relationship of the heart to the main bronchi and to the esophagus is reviewed. Metastases of primary extracardiac tumors reach the heart by direct extension or by the blood stream. An electrocardiographic examination should be made in every case of suspected cancer in order to detect myocardial involvement. The modification of the T wave does not have the characteristic evolution observed in myocardial lesions due to coronary sclerosis.

In the fourth part tumors of the pericardium are considered. Among the benign tumors, fibroma, lipoma, leiomyoma, lymphangioma and dermoid cysts are described. The malignant tumors of the pericardium (primary or metastatic) are associated with pericardial effusion (hemopericardium). Their symptomatology is reviewed and emphasis is placed on the x-ray picture and fluoroscopic examination.

The author believes that tumors of the heart are not rare and, if the internist looks for them as the neurologist looks for tumors of the brain, they will cease to be a pathologic curiosity.

Electrocardiography Including an Atlas of Electrocardiograms. By Louis N. Katz, A.B., M.A., M.D., Director of Cardiovascular Research, Michael Reese Hospital, Chicago. *Second edition.* Cloth. Price, $12. Pp. 883, with 525 illustrations. Philadelphia: Lea & Febiger, 1946.

The preface states that this edition has been expanded 50 per cent over the first, accomplished largely through the addition of more illustrations, summary tables, and a discussion of lead CF_5. But some of the length is attributable to a verbose and repetitious style which if corrected would not only shorten the book but make it more readable. The numerous illustrations, which are excellently reproduced, could be fewer in number, for many are examples of abnormalities adequately demonstrated in one or two illustrations rather than in six or seven, as is frequently done. The legends are too long and too detailed, and the main point to be emphasized is often thus obscured. References are numerous and up to date, but they are simply listed at the end of each section and not referred to in the text. There are an inordinately large number of typographical errors, considering that this is a second edition.

In the opening paragraph of section I there is a statement that "electrocardiographs are sensitive recording voltmeters." The string galvanometer is an ammeter. A little further on overshooting is ascribed to underdamping. Actually it is caused by the skin acting as a condenser with a by-pass resistance. These errors are typical of several others of an electrical and physiologic nature which occur in this section.

Section II, among other things, contains a description of electrocardiograms which bear such names as coronary pattern, heart strain pattern, digitalis pattern and rheumatic mitral pattern. There is also an axis shift pattern, the assumption being that with a certain contour of the electrical record one may say that the apex of the heart has been rotated upward and to the left (left axis shift) or downward and to the right (right axis shift). For this particular pattern this is oversimplification, for the record obtained will depend not only on rotation of the heart about its anteroposterior axis but also on rotation about its longitudinal and transverse axes and on local alterations in conduction and depolarization as well as on other factors. But the nomenclature the author uses to describe all these patterns has considerable significance other than from the point of view of electrocardiographic theory. By giving anatomic names to physiologic phenomena he has made a great appeal to the physician who welcomes this tenuous short cut to the cause of electrocardiographic abnormalities. It makes clinical electrocardiography easy, and he can disregard such "difficult" concepts as the electrical axis and the ventricular gradient. Incidentally the author also disregards these in his book after giving an erroneous definition of the latter. In short, the book gives impetus to an inaccurate and most deceptive practice—the making of anatomic and physiodynamic diagnoses from a purely electrophysiologic method.

That this is unsound the author paradoxically admits in numerous places throughout the book. Further, he emphasizes many times the lack of correlation between the electrocardiographic and the anatomic. For example, on page 393 he lists no less than twenty clinical entities which give a "coronary-like contour."

An otherwise good section on arrhythmias (III) is marred by inclusion of their clinical management. Treatment does not belong in a book titled "Electrocardiography." Further, the subject matter, particularly on the treatment of auricular fibrillation, contains some statements recommending the use of quinidine when emboli are occurring, and favoring rapid digitalization in myocardial infarction, to which most experienced clinicians would probably take vehement exception.

The beginner will find the length and wordiness of the volume a real obstacle to complete assimilation; the electrocardiographer will find the illustrations useful for reference and teaching but the text confusing because it is often contrary to what he has read elsewhere; the expert will find much with which he will disagree.

Pneumoperitoneum Treatment. By Andrew Ladislaus Banyai, M.D., F.A.C.P., F.C.C.P., Associated Clinical Professor of Medicine, Marquette University Medical School, Milwaukee, Wisconsin. Cloth. Price, $6.50. Pp. 376, with 74 illustrations. St. Louis: C. V. Mosby Company, 1946.

This monograph is a complete presentation of the subject of pneumoperitoneum. The material has been prepared with great care and is clearly and concisely presented. In the chapter devoted to historical review it is pointed out that the idea of pneumoperitoneum was conceived in 1872, when a laparotomy for another purpose revealed the presence of tuberculous peritonitis from which the patient subsequently completely recovered. For some time thereafter laparotomy became the standard treatment for tuberculous peritonitis. Although the exact mechanism of the therapeutic action was not understood, several theories were advanced. The idea of introducing oxygen or air through a needle into the peritoneal cavity was later conceived and has since been used to a considerable extent. In the chapter on the technic of pneumoperitoneum every step is presented in detail. The complications of this procedure are presented, such as air embolisms, accidental pneumothorax, mediastinal emphysema and scrotal pneumocele. Several chapters are devoted to the therapeutic application of pneumoperitoneum in such conditions as tuberculous peritonitis, tuberculous enterocolitis, pulmonary tuberculosis, bronchial asthma, bronchiectasis, pulmonary emphysema and pulmonary hemorrhage of nontuberculous origin. The author has had a large experience with this form of treatment and he presents the advantages, disadvantages and ultimate results so free from bias as to give the reader extreme confidence in his work. Seventy-four well chosen illustrations and approximately five hundred references are included. This book contains a great deal of information concerning pneumoperitoneum which has never before been assembled in one volume. It can be highly recommended to all physicians.

Clinical Laboratory Diagnosis. By Samuel A. Levinson, M.S., M.D., Ph.D., Director of Laboratories, Research and Educational Hospitals, Chicago, and Robert P. MacFate, Ch.E., M.S., Ph.D., Assistant Director of Laboratories, Research and Educational Hospitals, Chicago. Third edition. Cloth. Price, $10. Pp. 971, with 207 illustrations. Philadelphia: Lea & Febiger, 1946.

This is a complete handbook, including chapters on skin tests, pediatric procedure, tropical medicine, legal medicine and toxicology, histologic technic and such recently developed procedures as penicillin assay and kidney clearance tests with inulin and diodrast. An appendix with important general data and laboratory procedures has been added. The indexing is excellent, and the additional index for important laboratory tests in the common diseases should be very useful. Preceding the descriptions of the technical procedures are introductory remarks about the normal functions and clinical pathology of each organ or system. In places these explanations are not up to modern concepts or are too vague to be adequate. The book has an abundance of illustrations, most of them clear and well chosen. A smaller number of the pictures are actual photographs, which show the important structures clearly. The drawings are good and the student will profit from them more than from photographed specimens. Concerning laboratory methods, the value of certain tests (e. g. stomach tests) seems to be overstressed and could be simplified. A number of the older tests could be omitted. Instead of some of the simple methods with doubtful accuracy, the newer more accurate methods (such as enzyme determinations) may be preferred, though they involve more work and experienced technicians. Obviously this book was not written for the man engaged in medical research but for the technician, the medical student and the medical practitioner.

A Textbook of Gynecology. By Arthur Hale Curtis, M.D., Professor and Chairman of the Department of Obstetrics and Gynecology, Northwestern University Medical School, Chicago. Fifth edition. Cloth. Price, $8. Pp. 755, with 455 illustrations, chiefly by Tom Jones. Philadelphia & London: W. B. Saunders Company 1946.

This edition of Curtis's book, for years one of the best of the standard textbooks, is larger than the others, retains the balance, the fine illustrations and the high literary standards of its predecessors and has, of course, been brought up to date. It would be superfluous to recount the contents of the volume, for it is complete. The character of the book does require comment. Curtis has a remarkable gift for making the reader feel that he is in private conference with the author. After presenting both sides of debatable issues fairly, Curtis tries frankly to win the reader over to his view. In these days when textbooks tend to be thoroughly documented, encyclopedic, impersonal and rather dry, it is refreshing to encounter an author who makes no attempt to camouflage his personal opinion. The fact that Curtis admits gracefully and with good humor that he may be in error in these personal views seems only to give them added weight. At the same time there is established between author and reader a feeling of friendly familiarity which is the pleasantest quality of the work. Authoritative but not dogmatic, sound, yet up to date, excellently illustrated, this textbook may profitably be read by any one interested in gynecology.

Urologic Roentgenology. By Miley B. Wesson, M.D. Second edition. Cloth. Price, $5.50. Pp. 259, with 258 illustrations. Philadelphia: Lea & Febiger, 1946.

This edition of a work recognized as authoritative has been so thoroughly revised and rewritten as to constitute a practically new book. The plates have been gone over carefully and many old ones discarded and new ones added. The book is an intensely personal one, and the strong convictions and opinions of Dr. Wesson are prominent throughout. One instance is the statement in the section on intravenous urography that "no renal surgery should ever be performed before a diagnosis has been confirmed by a retrograde pyelogram." Many urologists consider retrograde pyelography unnecessary, and even detrimental, in many cases of renal stone and in most cases of hydronephrosis. Doubtful cases will, of course, always require a check by the retrograde method. A valuable feature of the book is the concise history accompanying most of the illustrations. The publishers have cooperated splendidly with the author. The quality of the paper is excellent, and in each of the photographs the pathologic condition is clearly demonstrated.

Queries and Minor Notes

The answers here published have been prepared by competent authorities They do not, however, represent the opinions of any official bodies unless specifically stated in the reply Anonymous communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted on request

DERMATITIS IN WOOLEN MILL WORKERS

To the Editor—Certain employees in our local woolen mills develop a dermatitis of a pustular nature when handling the dyes and chemicals The dyes used are all coal tar products, the chemicals are sodium bichromate, sodium sulfide, sulfuric acid, formic acid and acetic acid Please discuss measures to protect workers from these materials, such as some type of ointment for the hands and arms

John J Rouse, M D, Reedsburg, Wis

Answer—Dermatitis among dyers in woolen mills is not uncommon Most of it is due to sensitization to sodium bichromate, which is used as a mordant in the dye bath The other chemicals mentioned (sodium sulfide, sulfuric acid, formic acid and acetic acid) are all primary skin irritants in strong concentration and sensitizers in low concentrations

The best protective measures to be used by exposed workers are the wearing of impervious sleeves gloves and aprons These prevent contact of irritants with the skin Protective ointments are less effective and in some cases not practical because they may come off on the wool However, if protective ointments should be used, those of the water repellent type are the best Such types can be obtained in either the greasy form or the dry film form An ointment consisting of 70 parts of anhydrous lanolin and 30 parts of olive oil can be used for the greasy type of ointment The water repelling dry type of ointment consists essentially of about 10 parts of shellac dissolved in isopropyl alcohol with a filler of talc, titanium oxide and sodium perborate When applied to the skin, the alcohol evaporates and leaves a dry water repelling film of shellac in which is embedded the powders forming the white coating

EFFECTS OF REPEATED IRRADIATION

To the Editor—Dr A states that the skin "throws off" x ray effects after thirty days and that small doses of x rays (used to treat eczematous conditions of the hands) may be repeated indefinitely, provided at least a month elapses between treatments Dr B states that (1) the skin can tolerate only a certain amount of x-rays over any one area during a person's entire life that (2) no more should be given after this critical amount (1 200 1 600 roentgens) has been administered and that (3) the effect of radiation is cumulative and never lost, i e, if a quantity of radiation was given at 20 years of age and then at 30 years of age, the total effect would be almost as harmful as if all were given within a short period What is the present concept?

M D, Pennsylvania

[This question was referred to two consultants whose respective replies follow —Editor]

Answer—Dr B is correct The amount of roentgen radiation that is tolerated without grossly visible injury varies among individuals and depends on the size of the area exposed, the quality of the rays and the time over which the radiation is given In general, permanent damage is done by more than 1 200 roentgens Much smaller amounts may at times cause severe damage Only a certain amount can be tolerated by any one area throughout a lifetime

Answer—Exactly how much x rays the skin will tolerate is not known The average American dermatologist administers 75 roentgens of low voltage unfiltered x rays a week for a total of four to six weeks for the treatment of eczema of the back of the hands This course of treatment is not repeated for at least a month If it becomes necessary to administer further radiation the conservative dermatologist would not give to any one area of skin more than four courses of treatment (1,200 to 1 800 roentgens) More than this amount might lead to permanent radiation changes in the skin

If a quantity of x rays is administered which is just short of that required to produce radiodermatitis and ten years later a similar quantity is administered to the same area, radiodermatitis may ensue The effects of x-rays are cumulative It is unsafe to repeat small doses of x-rays indefinitely (See MacKee, G M and Cipollaro, A C X-Rays and Radium in the Treatment of Diseases of the Skin, ed 4, Philadelphia, Lea & Febiger, 1946)

CAUSE OF INFANT DEATHS ON THE ZEBULON B VANCE

To the Editor—In the Washington Letter in the June 15, 1946 issue of The Journal a paragraph entitled "Death of Babies Aboard Ship Traced to Virus Disease" appeared "Representative Jackson, Democrat of Washington, reports that the War Department has revealed the cause of the deaths of eight servicemen's babies brought to the United States on the 'brideship' *Zebulon B Vance* as a virus disease, pneumoenteritis The disease has never occurred in human beings in this country before, it is reported An army board of inquiry has absolved the medical staff of the ship of any negligence or misconduct regarding the deaths of the babies after arrival of the ship May 19 in New York from Le Havre" This spring an unusually severe type of infant diarrhea occurred in this locality The usual methods of treatment seemed ineffective, and the best we could do was to give them supportive treatment and hope that they would weather the storm Stool cultures were negative for the usual group of diarrhea organisms, and the possibility was considered that this might be the same disease as that on the "brideship" How was the conclusion reached that the epidemic diarrhea occurring on the ship was a new clinical entity? If it is a new clinical entity, how does it differ from the other diarrheal epidemics of suspected virus etiology in infants previously reported in this country? What were the autopsy findings?

Fred C Gregg, M D, Tucson, Ariz

Answer—Apparently the press report of pneumoenteritis in infants on the *Zebulon B Vance* was not founded on fact On inquiry, a statement from the Surgeon General's Office is as follows "It is our opinion at this time that this disease [on the *Zebulon B Vance*] is not a new clinical entity, as further studies have failed to support such a conclusion"

INDICATIONS FOR CONTACT LENSES

To the Editor—A middle aged mother of two children, who has worn glasses since she was 14, is near sighted and somewhat astigmatic She wants contact lenses What are the advantages and disadvantages of contact lenses?

M D, New York

Answer—Advantages Patients with keratoconus often can obtain but little improvement with common glasses Keratoconus, as its name implies, is a change (occurring most frequently during puberty) in which the cornea protrudes in its center, taking the shape of a cone The radius of curvature of the cornea in keratoconus is usually around 6 mm and often is combined with irregular astigmatism and sometimes with superficial central opacities Since the contact lens can correct these defects with a simple curved lens, the visual improvement is usually considerable

Myopic patients who have a spectacle correction above 6 to 8 diopters cannot see much more than 20/30, owing to the fact that ordinary lenses, as they are some distance from the eye, reduce the size of objects seen through them Many patients who have myopia even higher than that have a corneal curve of approximately 7 5 mm The contact lens does not diminish the size of the object seen through it, and, as patients with 7 5 corneal curvature can have a contact lens with a base curve of 8 5, the visual improvement is such that they frequently attain 20/20 vision

Patients with irregular or high astigmatism enjoy improved vision, since the corneal irregularity is replaced by a regular spherical curve Patients with one aphakic eye often do not have binocular vision even when the vision is 20/20 in both eyes, owing to two factors (1) The size of the image of the aphakic eye is approximately 25 per cent larger than the normal eye, (2) if the patient moves the eye behind ordinary lenses there is a prismatic effect that increases with the power of the plus lens If the difference in size is corrected with iseikonic lenses the prismatic effect with the movement of the eyes will still be present and will make it impossible to attain fusion on lateral and especially vertical movement of the eyes

Contact lenses diminish considerably the difference in the size of images received by the two retinas in aphakia and offer the best chance for fusion

Another advantage of contact lenses is to be found in cases of corneal opacities which are not too dense to prevent fair visual acuity These opacities are usually superficial and besides the irregular astigmatism produced, they disturb optical imagery especially because they are located just at the line of separation of the different indexes of refraction, i e, cornea 1 336 and air 1 00 This causes a more troublesome diffusion of light than if the opacity was located deeper in the cornea

The contact lens, by covering the corneal opacity, places it relatively deeper to the anterior refractive surface For practical purposes the index of refraction of the cornea is the same as the solution Therefore the opacities, instead of being in line of separation of the two indexes of refraction, become located deeper and as a result the blurring is lessened

Disadvantages Many patients who wear ordinary lenses of the usual type think they can be replaced by contact lenses Contact lenses do not give better vision than common glasses when the refractive error is of low degree Therefore, the patient will not see more with the contact lens than he would with his ordinary glasses A contact lens is a foreign body which should be well placed and well fitted to the eye It is not usually irritating if the fit and solution are correct and is not harmful to the eye, but often the patient feels as though he had something between the lids This introduces a new sensation to which the individual must become accustomed

The "liquid lens" i e the solution placed between the lens and the cornea infiltrates the corneal epithelium in the same way as water infiltrates the skin of the fingers when submerged a long time This causes blurring of vision The several solutions devised for this use have not as yet been perfected The blurring of vision usually appears three to four hours after the contact lens has been in place and when the lenses are removed from the eye the vision continues to be blurred for some time (usually fifteen minutes to half an hour) The employment of a contact lens requires a great deal of patience in coping with its adjustment, and those who can be benefited by these lenses are not always the ones psychologically suited for their use A good rule to follow is The more the patient needs the contact lens the better he is able to put up with its disadvantages

TREATMENT OF NEUROSYPHILIS

To the Editor —A woman aged 50 has a 4 plus blood Kline reaction and a 4 plus spinal fluid Kline reaction with a positive colloidal gold test She does not give a history of primary or secondary lesions Her general complaints are weakness and nervousness, and physical examination is entirely negative Should the Army 30-60-03 treatment be given or should the more recent treatment be employed which is being used universally by veterans' hospitals at this time for all types of syphilis? This treatment consists of a total dosage of 2,800,000 units of penicillin in individual doses of 25,000 units intramuscularly every three hours around the clock for fourteen days, dichlorophenarsine is given concurrently on the first, fourth, seventh, tenth and thirteenth days of treatment intravenously in dosages of 1 mg per kilogram of body weight to a maximum of 68 mg , bismuth subsalicylate in oil in individual dosages of 200 mg each given on the first, seventh and thirteenth days of treatment. Is the latter treatment justified, with the usual three month, six month, and one year follow up?

M D , Missouri

ANSWER —Before any treatment of this patient is undertaken she should (*a*) be examined by a competent neuropsychiatrist or by a syphilologist expert in the neuropsychiatric field and (*b*) she should have performed an adequate test of her spinal fluid, which includes a cell count performed on a freshly drawn specimen, quantitative estimation of protein content and complement fixation (Wassermann) test rather than any flocculation test and the details of the colloidal gold or other colloidal test should be known

From the inquirer's statement the only diagnostic comment which can be made is that the patient has neurosyphilis This is not, however, the important consideration in treatment Instead, it is essential that the attempt be made accurately to delineate the type of neurosyphilis which the patient has

In any case neither of the treatment systems suggested by the inquirer is suitable Almost certainly it is desirable for the patient to be treated with fever by means of induced tertian malaria, combined with the simultaneous administration of somewhere between 4 and 10 million units of penicillin

After treatment is given with fever plus penicillin, follow-up should extend over a period of many years rather than a single year or less

TREATMENT OF THROMBOANGIITIS OBLITERANS

To the Editor —A man with severe thromboangiitis obliterans has been relieved somewhat by Depropanex but has not improved very much Are there any new drugs that might be of value?

L O Simenstad, M D, Osceola, Wis

ANSWER —Unfortunately, medication is not available at present which is highly effective in the relief of thromboangiitis obliterans Depropanex, the product mentioned in the query, is a proprietary preparation consisting of a deproteinated pancreatic extract It is a saline solution of a protein free, nitrogenous fraction obtained by acid-alcohol treatment of beef pancreas free from insulin, histamine and acetylcholine This proprietary preparation is recommended by the manufacturers as a vasodilator and antispasmodic The reports on its use vary greatly, some favorable others that it is of little or no value Animal experiments with this product indicate that it is not absorbed following oral administration Injections of typhoid H antigen have been used for years as a vasodilator in cases of thromboangiitis obliterans with some benefit, but it has not proved uniformly successful, and there are certain disadvantages Increase of fluid intake with sodium chloride has been used to produce hydremia, with occasional beneficial results Xanthine derivatives or papaverine hydrochloride may be tried to relax spastic vessels or dilate collateral channels

A new drug which will be on the market soon, and which is already reported in the literature, namely, tetraethyl ammonium bromide, has given as promising results as any medical therapeutic measure yet developed In some cases injection of this chemical for three or four days has given relief over a period of several weeks

The surgical treatment of thromboangiitis obliterans must be seriously considered It is of special value before ulceration has occurred The efficiency of the collateral circulation may be greatly increased and in some cases the extremity, even when extensive ulceration is present, may be saved by lumbar sympathectomy

TRAUMA OF TONGUE AND POSSIBLE RHABDOMYOMA

To the Editor —A man aged 30 bit the anterior third of the dorsum of the tongue while eating Examination ten days later revealed a painless nodular, circumscribed mass 3 mm in diameter covered with normal epithelium Submaxillary adenopathy was not present The mass was removed Pathologic study showed traumatized striated muscle fibers in the deeper parts of the section which had undergone a certain amount of discoloration The continuation of these fibers toward the periphery showed pathologic changes, their nuclei had become large and vacuolated and each contained a large prominent nucleolus Syncytial formations containing such nuclei were seen Toward the mucosa especially around the vessels these cells were spindle shaped, and mitotic figures were seen

The possibilities have been considered that, as a result of the trauma the striated muscle has undergone a malignant rhabdomyomatous transformation or that this change may be a simple reaction to the trauma and will heal in time Is this a malignant manifestation or a normal muscle tissue reaction to the trauma? If it is suggestive, what treatment is advisable?

A Hovnanian, M D , Aleppo, Syria

ANSWER —There is no evidence in the pathologic report of any rhabdomyomatous transformation The appearances described are those of healing of injury to muscle and regeneration

22,000,000 VOLT ELECTRON TREATMENT OF CANCER

To the Editor —A patient with inoperable cancer has asked information about 22,000,000 volt electron treatment of carcinoma printed in a United Press story from Chicago July 18, 1946 Please discuss this treatment

Hamlin Mattson, M D , Minneapolis

ANSWER —As far as is known, cancer patients have not been treated with 22,000,000 volt electrons, nor have 22,000,000 volts of x-rays been used in the treatment of cancer

TISSUE THERAPY OF RETINITIS PIGMENTOSA

To the Editor —My attention has been called to the inquiry, on page 117 of the issue of Sept 14, 1946 under Queries and Notes on the tissue therapy of retinitis pigmentosa The statement is made that "as far as is known there are no ophthalmologists in this country using Filatov's technic or conducting investigations on his work" I have been intensively studying Filatov's work in relation to retinitis pigmentosa at the New York Hospital since June of this year So far the method has been used on over 40 patients It is entirely too early to offer any report on this work except that we have had some encouraging results and are going to continue the investigation along various lines to determine its merits and to work out plans of treatment I must emphasize the fact that the work is experimental and by no means in the "cure" stage Those samples of Filatov's work on "tissue therapy" which have appeared in this country have been sketchy and are not entirely up to American scientific standards in completeness or length of follow-ups The methods are not as simple as they sound, and we have run into some bad reactions Some of these in private practice could lead to legal difficulties The method merits further study both because of Filatov's good reputation and because of the few encouraging results which we have seen However, because of the very nature of this work it should be done only in a few large centers which have ample material and facilities to give it a fairly comprehensive test I believe that it will be found that this will lead to considerable modification of the method of usage and of the materials employed Even Filatov does not believe that his method is the last word in the therapy of retinitis pigmentosa It is still far from being an established therapeutic procedure and is not yet adaptable for ordinary office routine Retinitis pigmentosa is not a common disease It would certainly be unfair, and perhaps dangerous, for many individuals to attempt this investigative work on a mere handful of patients and then to draw conclusions

Dan M Gordon, M D , New York

To the Editor —Aided by a grant from the Council on Pharmacy and Chemistry of the American Medical Association and by another grant from the American-Soviet Medical Society, we are investigating and using Filatov's technic in the treatment of retinitis pigmentosa Our experiments are being done under controlled conditions and with special attention to dark adaptation studies of the retina The work is being carried out in the departments of ophthalmology and physiology of the New York Medical College, Flower and Fifth Avenue Hospitals

THERAPEUTIC "INFORMATION PLEASE"

The following eight papers were presented as a panel discussion, followed by a question and answer period, before a joint meeting of the Section on Internal Medicine and the Section on Experimental Medicine and Therapeutics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946. The panel fails to include the paper by Dr. Frank E. Adair on "Cancer," since the manuscript was not provided. The manuscripts are published without the bibliographies because of the somewhat informal manner of the presentation. Nevertheless the success of this panel discussion in attracting great numbers of listeners who were hearty in their approval of the presentation leads to its publication in this form. The Moderator was Dr. James A. Paullin, Atlanta, Ga.

HEMATOLOGY

CYRUS C. STURGIS, M.D.
Ann Arbor, Mich.

THERAPEUTIC EFFECT OF FOLIC ACID

One of the most outstanding advances in hematology since the introduction of liver therapy is the demonstration that crystalline synthetic folic acid, which occurs in its conjugated form as a component of the vitamin B complex, is effective in the treatment of macrocytic anemias with a megaloblastic bone marrow. Such anemias include addisonian pernicious anemia, sprue, nutritional anemia and the macrocytic anemia of pregnancy, of infancy and following total gastrectomy. It has not been proved to be of value in the treatment of other disturbances of the blood, with the possible exception of the leukopenia associated with nutritional states. When administered orally or parenterally to patients with pernicious anemia or allied macrocytic anemias, in doses of 10 to 20 mg. daily, it induces a prompt rise in reticulocytes of the circulating blood, a standard increase in the red blood cell count and hemoglobin and all the well known dramatic clinical manifestations of recovery observed in such patients when potent liver extract is given. The maintenance dose is unknown, but it may be as small as 20 mg. a week. Careful, long-continued clinical observations are essential to determine the ultimate place of folic acid in the treatment of the macrocytic anemias. At present, however, it can be said that the preparation is one of great promise which may completely supplant liver extract as a therapeutic agent, especially in those patients who are allergic to liver preparations. Its mode of action is concerned with accelerating the development of the immature red blood cells in the bone marrow and perhaps with the metabolism of nucleic acid in these cells.

EFFECT OF RADIOACTIVE ELEMENTS AND "DEMA"

Radiophosphorus, which loses one half of its output of beta radiation every fourteen and three-tenths days, is effective in the treatment of polycythemia vera when given intravenously or orally as sodium acid phosphate, in doses of 5 to 10 millicuries. Either spray roentgen ray therapy or radiophosphorus when given alone or in the initial stages of treatment in combination with phlebotomy reduces the red blood cell count to normal. It may be held at this level by the application of either one of these agents at intervals of six months to a year or more. These forms of treatment are undoubtedly the most effective ones for the disease. No claim can be substantiated, however, that radioactive elements at present can produce superior results to roentgen therapy either in leukemia or in the lymphoblastomas.

The use of "Dema," one of the nitrogen mustards, with the formula bis (chloroethyl) methylamine hydrochloride, is still in the experimental stage as a form of treatment for Hodgkin's disease, leukemia, and polycythemia vera. The action of this substance is similar to that of roentgen rays. It has extremely serious toxic effects on the peripheral blood and the bone marrow, but when carefully controlled may prove to be a useful form of therapy for patients with these disorders who become resistant to the roentgen ray.

STUDIES ON BLOOD PLASMA

Extensive use in the last war has demonstrated that plasma may be preserved indefinitely by freezing and dehydration without important changes and when needed can be reconstituted and injected intravenously with gratifying results in the treatment of shock. The remarkable advances in the chemical fractionation of the blood plasma, largely through the work of Cohn, are too comprehensive to discuss in detail. This investigator and his associates have demonstrated that the various components of the plasma can be separated in five main types chemically, and specific functions have

---

From the Department of Internal Medicine and the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan.

been ascribed to each of them. These are concerned primarily with the maintenance of fluid balance between the blood and the tissues of the body and hence are closely related to shock and formation of edema; with immunity to such diseases as measles and infectious hepatitis; with the isoagglutinins responsible for the blood types; with the various components of the clotting mechanism; with the antihemophilic globulin; with the maintenance of normal blood pressure and perhaps with the production of hypertension; with various enzymes and proteins, and with the group of lipoproteins which undoubtedly play an important role in various essential functions of the body.

THE RH FACTOR

The discovery of the Rh factor in 1940 by Landsteiner and Wiener has provided an explanation for certain hitherto obscure hemolytic reactions to blood transfusions and made clear the etiology of almost all cases of erythroblastosis fetalis, a commonly fatal hemolytic anemia of the newborn or of the fetus in utero. The practical implications are that the 15 per cent of the population who are Rh negative should never receive transfusions of other than Rh-negative blood if severe and sometimes fatal reactions are to be avoided; and that an Rh-negative woman who is impregnated by a Rh-positive man has 1 in 25 chances, or less, after the first pregnancy, of bearing a child with erythroblastosis fetalis. If the complications are to be avoided, it is imperative to determine the Rh type of all persons, male or female, who are to receive a blood transfusion, and of all women who are pregnant. An Rh-negative person should always receive Rh-negative blood as a transfusion.

VITAMIN K AND HEMORRHAGE

The observation that a hemorrhagic tendency may be due to a deficiency in prothrombin, one of the essential components of the clotting process, is of clinical importance. This deficiency is the cause of the hemorrhagic condition associated with obstructive jaundice, with hemorrhagic disease of the newborn, with certain states which interfere with intestinal absorption, such as sprue and ulcerative colitis, and with extensive hepatic disease. It is now well established that prothrombin cannot be formed by the liver unless vitamin K is present. The administration of vitamin K to the pregnant woman in the form of menadione, in doses of 2 mg. daily, during the last week of pregnancy will prevent hemorrhagic disease of the newborn due to hypoprothrombinemia. Of great importance also is that the parenteral administration of vitamin K preparations will eliminate the bleeding tendency associated with obstructive jaundice and thereby remove the extra hazard to surgical treatment of patients with this condition. In general it may be stated that the administration of vitamin K preparations, especially when the preparations are given parenterally, will control the hemorrhagic state due to hypoprothrombinemia in all conditions except that associated with hepatic disease.

DIAGNOSTIC VALUE OF STERNAL PUNCTURE

Information obtained from sternal puncture confirms the diagnosis in two thirds of the patients with hematologic disorders and presents a specific picture in about 1 of 6 such patients. In the latter group are patients with multiple myeloma, leukemia, addisonian pernicious anemia and allied conditions, agranulocytosis, lipoid histiocytosis and various parasitic diseases such as malaria and leishmaniasis. Useful information is obtained in polycythemia and hypochromic, aplastic, hemolytic and myelophthisic anemias. There are two points for emphasis: 1. Positive are more reliable than negative findings. 2. An experienced observer must interpret the findings.

THE BLOOD BANK

The undoubted value of the blood bank has been established in the past few years. It should be a part of the equipment of every hospital. Two main advantages result from a well conducted system for the storage of citrated blood. In the first place, it provides an almost unlimited amount of tested, typed blood which can be stored for at least seven days and which is immediately available for use. Second, it reduces materially the cost of blood transfusions to the patient. This means that many patients can be given multiple transfusions which otherwise might not be available. With the ease that blood may be secured for this purpose, it should be kept in mind that adult males without bleeding may develop hemochromatosis following multiple transfusions. This results from the inability of such patients to excrete iron once it has been injected into the vascular system.

CONTROL OF ANEMIAS OF PREGNANCY

It has been demonstrated in recent years that a macrocytic or microcytic anemia of pregnancy, more severe than the physiologic anemia of that state, occurs in from 20 to 30 per cent of all gravid women. Furthermore, it should be emphasized that such anemias can be controlled or prevented in a great majority of instances if the patient is given 5 grains (325 mg.) of ferrous sulfate three times daily and partakes of a general average diet containing an adequate amount of protein, the minimum being provided by one serving of lean meat, a quart of milk and an egg daily. For the sake of the mother and the child, such simple, harmless and efficient measures should be instituted universally as soon as a pregnancy is recognized and should be continued throughout lactation.

Occasionally certain nutritional macrocytic anemias, sometimes associated with pregnancy, are refractory to refined preparations of liver when given parenterally. They respond favorably, however, to the oral administration of liver extract. The practical importance and the etiologic implications of this observation have been emphasized recently by Watson and Castle.

STUDIES ON AGRANULOCYTOSIS

Agranulocytosis is probably always due to sensitivity to a drug, the most common causative agents being aminopyrine, the sulfonamide compounds, arsenic and antithyroid drugs such as thiouracil. The syndrome develops in only a small percentage of the patients receiving these preparations, however. The mortality among untreated patients exceeds 50 per cent. Early elimination of the responsible drug and the prompt administration of penicillin in doses of 40,000 units every two hours, intramuscularly, should reduce the mortality rate almost to zero.

TROPICAL MEDICINE

ERNEST CARROLL FAUST, Ph.D.
New Orleans

The year 1939 may be regarded as the beginning of the modern era in the prevention and treatment of diseases which are particularly prevalent in warm climates. Previous to this time effective immunization was available against typhoid and the paratyphoid fevers, smallpox, tetanus, spotted fever and yellow fever, while immunization against plague and cholera had as yet not been critically evaluated. Quinacrine (Atabrine) had been demonstrated to be therapeutically a good substitute for quinine, and there were moderately satisfactory drugs for the treatment of amebic dysentery, yaws, relapsing fever, schistosomiasis, hookworm disease, African trypanosomiasis and kala-azar. Pyrethrum and rotenone were recognized as good insecticides. Yet five hundred million human beings were suffering from malaria each year; typhus, plague and cholera were killing hundreds of thousands annually, and other common tropical diseases were taking a heavy toll.

Increased communication with the tropics, particularly by air transport, was providing accelerated stimulus to control diseases in these hyperendemic areas, since they were retarding commercial development and conceivably might be imported into relatively clean communities in America and Europe. The problem of protecting health and even life itself became more imperative when World War II compelled the training of troops and the carrying out of military operations in practically all parts of the globe where tropical diseases were prevalent. Intensive, intelligent cooperation in experimental research between military and civilian groups in the United States and the British Commonwealth, as well as courageous clinical investigation, on a scale previously unconceived, made possible the rapid strides which have taken place in the prevention and treatment of tropical diseases.

PATHOGENESIS AND SYMPTOMATOLOGY

Investigation on the pathogenesis of many diseases has provided a clearer interpretation of their symptoms, particularly during the incubation and early clinical stages. Bancroft's filariasis, schistosomiasis, scrub typhus and Bullis fever have afforded abundant material for clinical study, while sandfly fever has been observed after both natural and experimental exposure of substantial groups of persons.

DIAGNOSIS

Concentration technics have been improved for the more certain recovery of Schistosoma eggs from patients' excreta and of microfilariae from blood and other fluids of the body. Species-specific serologic and immunologic methods have been perfected for the diagnosis of epidemic and murine typhus, spotted fever, scrub typhus, Q fever, amebiasis, bartonellosis, kala-azar, oriental sore, espundia and Chagas' disease, while better group-specific antigens have been developed for the diagnosis of Bancroft's filariasis, onchocercosis and schistosomiasis.

IMMUNIZATION

In plague the Haffkine type of vaccine has been improved so as to confer protection on fourfold as many persons as among the uninoculated, while the Otten type of vaccine, employing avirulent living Pasteurella pestis, has been demonstrated to provide 80 to 90 per cent protection among several millions inoculated in Java, South Africa and Madagascar. By the selection of highly virulent strains of cholera vibrios, vaccines have been prepared and administered to hundreds of thousands of persons in Burma and India, with evidence of about 90 per cent protection in comparison with high susceptibility to the disease observed among uninoculated controls. Immunization against typhus with the Cox egg yolk sac vaccine and the Castañeda mouse lung vaccine has greatly reduced infection among exposed persons and has reduced mortality among the immunized almost to the vanishing point. There is now the prospect of satisfactory immunization against scrub typhus, dengue fever, and possibly sandfly fever.

TREATMENT

1. *Antimalarials.*—Quinacrine has been demonstrated to be not only an eminently satisfactory substitute for quinine in the treatment of clinical malaria, but in daily doses of 1.5 grains (0.1 Gm.) is known to provide almost solid suppression of the disease for persons in highly malarious areas. Although this drug will not prevent the breaking through of vivax infection subsequent to the cessation of suppressive treatment, it almost invariably eradicates the falciparum parasite, thus controlling the most widespread and most commonly dangerous disease in the tropics.

Two new antimalarials, chloroquine (7-chloro-4-[4-diethylamino-1-methylbutylamino] quinoline) and paludrine (N_1-para-chlorophenyl-N_5-isopropylbiguanide acetate) will soon be available commercially for clinical use, after long experimental and preliminary clinical tests. In the United States alone more than fourteen thousand natural and synthetic substances have been tested as potential plasmodicides, with clinical study on eighty of the most promising. Chloroquine ("Aralen," Winthrop Chemical Company, Inc.) has been found to be superior to quinacrine in several respects: It produces less gastrointestinal irritation, apparently causes no psychotic disturbances, leaves no discoloration of the skin and in therapeutic doses is well tolerated and highly effective in producing more rapid symptomatic relief, fewer relapses and longer periods between relapses in vivax infection. A full course of treatment consists in the oral administration of 9 grains (0.6 Gm.) the first day and 4.5 grains (0.3 Gm.) on the three following days. For suppressive therapy one 4.5 grain tablet each week is apparently adequate to prevent a clinical break-through. Paludrine (Imperial Chemical Industries, Ltd.) has not as yet received as thorough clinical testing as chloroquine but promises to be considerably better than quinacrine.

Thus far, no antimalarial has been discovered which has been proved to be a true prophylactic, although a plasmoquin derivative now under clinical study may possibly serve this end.

As a corollary to advances in specific antimalarials, the recent recognition of algid malaria as a variety of medical shock, in which there is pronounced dilatation of the smaller blood vessels, suggests a rationale for successful management of a patient with this type of malaria.

2. *Leishmanicidal Drugs.*—Antimony and potassium tartrate (tartar emetic) was the first drug to be used

successfully in the treatment of leishmaniasis (mucocutaneous variety). It soon became the drug of choice in kala-azar (visceral leishmaniasis), although the less stable antimony and sodium tartrate (B. P.), when freshly prepared, is equally effective and is better tolerated. Since 1915 several synthetic pentavalent antimonials have been given careful clinical trial (Stibenyl [the sodium salt of acetyl-*p*-aminophenylstibinic acid], Stibosan [sodium meta-chloro-para-acetylaminophenylstibinate], Neostam [stibamide glucoside], Urea Stibamine, Aminostiburea, Neostibosan, Distibinyl and solustibosan). Of this group Urea Stibamine (the carbamide salt of para-amino-phenyl-stibinic acid) and Neostibosan (diethylamino-*p*-amino-phenyl stibinate) have become standard prescriptions. More recently solustibosan (sodium antimonyl gluconate; Bayer 561; "Stibanose," Winthrop Chemical Company, Inc.; "Stibatin," Glaxo Laboratories) has been tested both in experimentally infected golden hamsters and in clinical cases and has proved to be as highly effective and as well tolerated as Urea Stibamine and Neostibosan.

In the Egyptian Sudan a severe type of kala-azar has frequently been refractive to pentavalent antimonials, while cases of antimony-resistant kala-azar are not uncommon in China, India and other endemic foci. The aromatic diamidines, particularly Stilbamidine, Pentamidine and Propamidine, are useful in these cases. Both in experimental tests and in the clinic, Stilbamidine (4,4′ diamidino stilbene) has been demonstrated to be therapeutically the equal of Neostibosan in the average case of visceral leishmaniasis and to be curative in antimony-resistant infections. Because of the high toxicity of the aromatic diamidines, great caution must be exercised in their administration.

3. *Trypanosomicidal Drugs.*—Although continued clinical study has been made of new arsenicals and other drugs in the treatment of African trypanosomiasis, nothing has been found which promises to supplant tryparsamide (Merck) or suramin sodium (Bayer 205; Naphuride, Winthrop Chemical Company, Inc.). However, the aromatic diamidines, especially Pentamidine (4,4′-[pentamethylenedioxy]dibenzamidine), Stilbamidine and propamidine (4,4′-[trimethylenedioxy] dibenzamidine), which were synthesized with the hope that they would be curative in human trypanosomiasis, have been found to produce cures in cases of early disease and thus may prove to be helpful substitutes in arsenic-fast infections or those with severe optic neuritis. Moreover, in highly endemic areas Bayer 205 has been employed prophylactically, and a single administration of 1 Gm. provides trypanosome-free blood for as long as four months.

4. *Antiamebic Drugs.*—In a recent critique on the treatment of amebiasis, a distinguished British investigator has reached the conclusion that no antiamebic drug thus far employed is "infallible in sterilizing a gut infection of E. histolytica, though there is evidence that each of them may contribute something to this end."

Emetine hydrochloride (U. S. P.) is the only drug known to eradicate extraintestinal amebiasis. It is likewise useful in controlling acute amebic dysentery, but in a high percentage of cases is not curative. The parasites tend to become resistant to this drug and perhaps even to other drugs now used in the treatment of amebiasis. Because of these effects and because of its high toxic factor, the use of emetine hydrochloride should be restricted in intestinal amebiasis to a minimum number of injections required to reduce severe symptoms, and the drug should never be employed in the treatment of mild or asymptomatic infections. Emetine bismuth iodide (B. P.) has been used for oral administration in amebic colitis and is regarded by British physicians as superior to most other drugs for this purpose.

Arsenicals: When acetarsone (Stovarsol; acetylaminohydroxyphenylarsonic acid) was introduced by French workers for the treatment of amebiasis, it proved to be a useful alternative to ipecac and emetine. More recently it has been supplanted by carbarsone (U. S. P.) (4-carbamino-phenyl arsonic acid), which is probably equally effective and is much better tolerated. In dogs acutely ill from experimental infection with human strains of Endameba histolytica carbarsone has been found to exhibit a 75 per cent rate of cure and in monkeys a 42 per cent rate. Recent tests with carbarsone oxide (*p*-carbamino-phenyl arsenous oxide) on amebiasis in monkeys and in a few clinical cases have demonstrated that it is potentially a promising amebicide. Other types of antiamebic drugs must be employed in the treatment of those persons who manifest intolerance of arsenic.

Compounds of Iodine: In 1921 chiniofon (U. S. P.) (iodoxyquinoline sulfonic acid) was introduced clinically for the treatment of amebiasis, under the German name "Yatren," and was found to be highly effective in cases of acute as well as of chronic amebic colitis. Its oral administration has been frequently supplemented by high retention enemas of solution of chiniofon. Both in experimentally infected dogs and in human infections its rate of cure is high (dogs, 100 per cent; human beings, about 90 per cent). It is well tolerated except for the production of a watery stool in some cases, but this is not necessarily a contraindication to its continued use unless the patient is severely dehydrated. Vioform (U. S. P.) (iodo-chloro-hydroxyquinoline) was first advocated as a specific for the treatment of amebiasis in 1933. It has a high amebicidal rate both in experimental animals (monkeys, 87.5 per cent) and in human beings. Its clinical usefulness has probably not been sufficiently emphasized. A third compound, diodoquin (N. N. R.; G. D. Searle & Co.) (5,7-diodo-8-hydroxyquinoline), has more recently been given extensive clinical use. Although it has a higher iodine content than chiniofon and vioform, it is absorbed from the wall of the bowel much more slowly. Its action is correspondingly slower, so that three weeks instead of five to seven days are required for a full course of treatment. Physicians who have given this drug thorough trial rate it between 85 and 99 per cent curative. It has essentially no contraindications.

A great deal of recent effort has been given to the isolation of certain active fractions of chaparro amargoso (Castela nicholsoni texana), the Mexican medicinal plant which empirically has been found to have antiamebic properties. The results are not yet sufficiently advanced for critical evaluation.

5. *Schistosomicidal Drugs.*—Effective treatment for schistosomiasis began in 1918 with the use of antimony and potassium tartrate, U. S. P. (tartar emetic). This drug was partially supplanted in 1929 by the trivalent antimonial, fuadin (sodium antimony III bis-catechol-

2,4 disulfonate) (stibophen B. P.), which is administered intramuscularly instead of intravenously and is on the whole better tolerated. A few years later (1936) Anthiomaline (antimony and lithium thiomalate) was introduced by French investigators for treatment of schistosomiasis. Experimentally and in a few clinical cases the pentavalent Neostibosan has also been tested. In animals all these drugs have appreciable effect on Schistosoma mansoni, but none of them clears the infection. Clinically fuadin has a high relapse rate (70 per cent) in schistosomiasis japonica following a schedule of treatment employing 0.566 Gm. of metallic antimony (which is considerably more than the recommended dose), while antimony and potassium tartrate, administered as a 0.5 per cent solution and totaling approximately the same amount of antimony (0.565 Gm.), has provided the impressively lower relapse rate of 16 per cent. Both experimentally and in the hands of some physicians with patients having schistosomiasis Anthiomaline has failed to sustain its previous reputation, but other physicians regard it with confidence.

It is important to remember that antimony therapy is highly toxic for the liver, as indicated by increased elevation of the icteric index with successive courses of treatment.

Clinical investigators in South and West Africa have treated vesical and Manson's schistosomiasis by intensive administration of antimony. One series of 100 patients has been given antimony and sodium tartrate, 1.5 per cent solution in saline and dextrose solution, at 9 a. m., noon and 3 p. m. on two consecutive days, for a total dosage of 12 mg. per kilogram of body weight. Few side effects were encountered, and three months later Schistosoma eggs were not found in urine or stool. In another series (46 cases) fuadin (stibophen B. P.) was administered in the amount of 0.46 grain (30 mg.) daily for two weeks (omitting Sundays), and Anthiomaline (May and Baker), in the amount of 0.49 grain (31.9 mg.) daily for the same period of time. Only 4 members of this group were considered not cured.

New drugs with considerably better promise than antimonials for the cure of schistosomiasis are still under experimental trial. These include certain aminoanthraquinones and phenothiazines, which provide 60 to 90 per cent clearance of the worms in seven days, with 100 per cent survival of the experimental hosts. Only one newly tested antimonial has thus far shown as satisfactory results.

In general, it is important to note that S. japonicum infection, the most serious type of human schistosomiasis, is the most difficult to eradicate.

6. *Filaricidal Drugs.*—Intensive experimental and clinical tests with several antimonials and arsenicals, as well as other preparations, have failed to demonstrate direct lethal action on the parent worms in cases of Bancroft's filariasis. However, there is some evidence that a sustained reduction in the number of circulating microfilariae and their complete elimination in peripheral blood over a period of time indicate bona fide filaricidal as well as filaristatic activity. Fortunately the great majority of American military personnel who showed early manifestations of the disease following exposure in the South Pacific area have recovered without the appearance of chronic lesions.

7. *Anthelmintics for Intestinal Helminthiases.*—No new drugs have been introduced within recent years. Crystoids anthelmintic (a pill containing hexylresorcinol) is satisfactory for treating ascariasis and is helpful in removing hookworms. Tetrachlorethylene (U. S. P.) is commonly indicated for hookworm infection but has not been particularly successful in the Southwest Pacific where Ancylostoma duodenale as well as Necator americanus were encountered. Gentian violet medicinal (U. S. P.) is the drug of choice for strongyloidiasis (coated with one and one-half hour Seal-Ins) and for oxyuriasis (coated with four hour Seal-Ins or Enseals). Oleoresin of aspidium (U. S. P.), fresh, is first choice and carbon tetrachloride (U. S. P.) second choice for tapeworm infections.

8. *Antirickettsial Therapy.*—For clinical treatment in the typhus group of diseases considerable success has been achieved by the use of immune serum early in the disease. More recently, however, para-aminobenzoic acid has been demonstrated to be relatively specific when administered during the first week following the onset. This therapy has been employed in epidemic typhus, spotted fever and scrub typhus (tsutsugamushi disease). The drug is administered orally in powder form, partly neutralized by sodium bicarbonate to lessen gastric acidity. In order to maintain an average blood plasma level of 30 to 60 mg. per hundred cubic centimeters an initial dose of 8 Gm. is followed by doses of 3 Gm. every two hours. The results consist of (1) decrease in about twenty-four hours and relatively rapid disappearance of toxic manifestations; (2) drop in temperature in about two days; (3) reduction in complications, as bronchitis, pneumonitis, myocarditis and hemorrhage; (4) minimal leukopenia and granulocytopenia; (5) shortening of the period of convalescence, and (6) a practical guarantee that fatalities can be eliminated.

9. *Sulfonamide Therapy.*—The sulfonamide drugs have produced satisfactory results when employed in bacillary dysentery, cholera and plague.

In bacillary dysentery treatment with sulfonamide compounds is particularly effective in the acute condition but is also valuable in chronic disease and for carriers. Sulfanilamide, sulfaguanidine and sulfapyridine have the lowest shigellicide ratings. Succinylsulfathiazole (Sulfasuxidine) and phthalyl sulfathiazole (Sulfathalidine), as well as sulfanilyl benzamide, are all well tolerated and clinically effective. Sulfanilyl benzamide apparently has low toxicity and is highly absorbable. Sulfathiazole and sulfanilyl benzamide are particularly useful against the Sonné type of the disease. Sulfadiazine has been found to be the most efficient clinically and is more effective than other sulfonamide compounds in eliminating Flexner type organisms in carriers. It may be advisable to give sulfadiazine prophylactically during epidemics. However, during epidemics of bacillary dysentery (Flexner types), evidence has been produced that the organisms become sulfonamide-fast.

Sulfonamide drugs are contraindicated for complicating infections in the typhus group of fevers when para-aminobenzoic acid is being administered.

In cholera considerable success has attended the combined administration of blood plasma to combat shock and sulfonamide drugs. Sulfaguanidine is possibly somewhat superior to sulfapyridine and sulfathiazole; moreover, if administered at the onset of the disease, sulfadiazine plus plasma may be depended on to be 100 per cent effective in assuring recovery of the patient. In Indian villages in cases of untreated cholera fatality ranges from 40 to 70 per cent. Patients who are hospitalized and are given isotonic solution of sodium chloride and supportive treatment average about 15 per cent mortality. Treatment with isotonic solution of sodium chloride and sulfonamide drugs reduces the rate to 2 per cent. Previous cholera vaccination within ten to twelve months provides about 90 per cent protection and lessens the severity of the disease for those who contract it.

In plague, immune serum and sulfonamide drugs have greatly reduced the expected mortality. In field tests at Latur in Bihar State, India, the death rate was 53.6 per cent in 149 controls (all types) as contrasted with 23.5 per cent in 157 persons treated with immune serum, 27.0 per cent in 122 persons treated with sulfapyridine, 20.8 per cent in 230 persons treated with sulfathiazole cases and 20.0 per cent in 60 persons treated with sulfathiazole plus antiserum. The comparable mortality percentages for patients with severe septicemia were: 96.4 (56 patients), 69.0 (42 patients), 72.2 (36 patients), 55.1 (65 patients) and 38.1 (21 patients). All cases of pneumonic plague had a fatal termination irrespective of therapy. In a 1944 epidemic in Karnal, United Provinces, India, 80 per cent of persons not treated died, and 21 per cent of those given sulfathiazole. It was found that with sulfonamide therapy the prognosis is good if treatment is begun on the first day of illness and is continued for a week to ten days without interruption. Fatalities invariably were due to beginning the treatment late and to incomplete or interrupted treatment. In primary bubonic plague, with appropriate sulfonamide therapy undertaken at the onset of the disease, the prognosis is excellent. Vaccinated persons who are exposed and acquire the disease may not survive if they are not adequately treated.

10. *Penicillin Therapy.*—Penicillin has proved to be specific for the common tropical spirochetal diseases, yaws (frambesia), pinta and relapsing fever, as well as leptospirosis. It thus provides a valuable alternative for the treatment of persons whose disease is arsenic-fast or who cannot tolerate arsenic. This antibiotic is also valuable as an adjuvant in combating certain complications in the typhus group of diseases, when sulfonamide compounds are contraindicated because they neutralize the action of para-aminobenzoic acid. Finally, penicillin has been found useful in reducing certain intestinal bacteria and in indirectly simplifying the treatment of amebic colitis.

Penicillin is not specifically effective in human or avian malaria, amebiasis, bacillary dysentery, cholera, plague, the typhus group of diseases, leishmaniasis, trypanosomiasis or helminthic infections.

INSECTICIDES AND REPELLENTS; RATICIDES

Insecticides.—With the outbreak of World War II the military needs for dependable insecticides pyramided to fantastic proportions. In medical entomology there was need for larvicides to control the breeding of malarial, filarial, dengue and yellow fever mosquitoes, as well as to combat louse infestation. Oiling of breeding places and treatment with paris green were moderately effective in controlling mosquito breeding, and pyrethrum sprays were relatively satisfactory in killing adult mosquitoes. The pyrethrum aerosol bomb provided definite improvement in the use of pyrethrum for individual use in military groups stationed in highly endemic areas of malaria. Then supplies of pyrethrum from the Near East and Japan were cut off. Fortunately a German insecticide with a Swiss patent, which was originally designed for agricultural entomology, was found to be highly effective in killing larval and adult mosquitoes, filth flies and body lice, and relatively helpful in reducing exposure to diseases transmitted by fleas and ticks. This chemical is dichlorodiphenyltrichloroethane, familiarly known as DDT. Once its usefulness for the control of arthropods of medical importance had become established it was manufactured in the United States by the millions of pounds.

DDT has been an important agent in reducing malaria among troops in the Southwest and Western Pacific theaters; in reducing the hazard of enteric diseases which are carried by filth flies, as in Manila after American reoccupation, and in bringing to a rapid termination mass epidemics of typhus and of louse-borne relapsing fever which threatened the civilian populations of Naples and other cities in the Mediterranean area. More recently DDT has been demonstrated to be rapidly lethal to adult sandflies, thus providing a practical method for eliminating exposure to kala-azar, Oriental sore, espundia, bartonellosis and sandfly fever. Its effect is on the peripheral nerve endings of insects which make direct surface contact with it. If ordinary precautions are taken, DDT is relatively harmless to higher animals and human beings.

Even more effective insecticides will soon be commercially available. These include dichlorodiphenyldichloroethane (TDE) (Rhothane), which is not more than one fourth as toxic to warm-blooded animals as is DDT but is more toxic, on immediate contact, to mosquito larvae and has more prolonged effect; and beta-butoxy-betá-thiocyano-diethyl ether (Lethane 384), which is safe and highly effective for household disinfestation against mosquitoes, flies, fleas, cockroaches, bedbugs, clothes moths and weevils.

Repellents.—Dimethyl phthalate has been developed for rubbing on exposed skin to repel mosquitoes. It produces no dermatitis and its action lasts for several hours. Dimethyl phthalate, dibutyl phthalate and particularly benzyl benzoate have been emulsified in various detergents to impregnate clothing, so as to prevent infestation with chiggers which transmit scrub typhus and to reduce the hazard of invasion of the skin with the cercariae of Schistosoma when one is wading in infested water in endemic areas. After several washings with strong laundry soap benzyl benzoate impregnation will retain its repellent action for mites and its lethal action for schistosome cercariae. This same drug has been demonstrated to be effective in the treatment of scabies.

Raticide.—Sodium fluoroacetate has been field tested and found to be highly poisonous to rats when mixed with bait to which domestic and wharf rats have access. It is reported to be superior to red squill, barium carbonate, thallium sulfate and arsenic trioxide, but is highly toxic for domestic animals and man.

SUMMARY

Since 1939 important developments have taken place in the field of tropical medicine. This has resulted in part from accelerated commercial contact with tropical countries but is due in an even greater degree to military needs of World War II. Much has been learned about the pathogenesis of disease, particularly Bancroft's filariasis, schistosomiasis, scrub typhus, Bullis fever and sandfly fever. Valued aids have been perfected for the diagnosis of schistosomiasis, filariasis, the typhus group of diseases, amebiasis, bartonellosis, kala-azar, oriental sore, espundia and Chagas' disease. Effective immunization has been developed for typhus, while plague and cholera vaccines have been improved. Protective vaccines for scrub typhus, dengue and possibly sandfly fever may soon be developed.

In the realm of therapy the claims for quinacrine hydrochloride as a good antimalarial have been amply demonstrated. This drug is not only the equal of quinine in the treatment of clinical malaria but has proved to be highly satisfactory as a suppressive agent. Of the thousands of natural and synthetic substances which have been tested as potential plasmodicides, two, chloroquine (7-chloro-4-[4-diethylamino-1-methylbutylamino] quinoline) and paludrine (N_1-para-chlorophenyl-N_5-isopropylbiguanide actetate) will soon be available commercially. Both of these promise to be superior to quinacrine. Solustibosan (sodium antimonyl gluconate) and Stilbamidine (4,4′-diamidino stilbene) are new drugs which are effective in the treatment of kala-azar. Suramin sodium (Naphuride; Bayer 205) has been found useful as a prophylactic in African sleeping sickness. No new amebicidal drug has been developed since 1936, when diodoquin was introduced. While antimony and potassium tartrate is still the best available therapeutic drug for schistosomiasis, experimental studies indicate the possibility that another antimonial and certain amino-anthraquinones and phenothiazines have more specific action against schistosomes. No eminently satisfactory treatment has been developed for filariasis and no new drugs have been discovered for the intestinal helminthiases.

Para-aminobenzoic acid has proved to be relatively specific in the treatment of the typhus group of diseases, while sulfonamide drugs have been found to be useful in bacillary dysentery and plague, and 100 per cent effective in cholera when administered together with plasma. Penicillin is specific in yaws, pinta, relapsing fever and leptospirosis.

On the preventive side the discovery that DDT is an effective insecticide against mosquitoes, filth flies, lice and other arthropod transmitters of diseases has made possible the rapid control of malaria, filariasis, dengue, enteric diseases transmitted by filth flies, and typhus and relapsing fever contracted as a result of louse infestation. New, more powerful insecticides are on the horizon. Dimethyl phthalate, dibutyl phthalate and benzyl benzoate have proved to be highly effective repellents in warding off mosquito-transmitted diseases, and when impregnated in clothing greatly reduce exposure to scrub typhus and schistosomiasis. Finally, sodium fluoroacetate has been demonstrated to be superior to other poisons for eradicating domestic and wharf rats.

INFECTIOUS DISEASE

HOBART A. REIMANN, M.D.
Philadelphia

Needless to say, most of what is new in the treatment of infectious diseases revolves about antibiotic agents. So rapid has progress been made that sulfonamide compounds are now regarded as old fashioned in the treatment of certain diseases and immune serums are nearly obsolete. Not only are the benefits of penicillin and sulfonamide compounds reflected in the great reduction of the morbidity and mortality rates of diseases caused by bacteria sensitive to these agents, but there has also been a decline in the mortality of degenerative diseases due to the control of intercurrent infections. It is safe to predict a further decline in the years to come in the incidence of chronic cardiovascular-renal and other degenerative diseases which often originate from or are incited by infections, particularly those caused by hemolytic streptococci.

There is, unfortunately, an obverse side to a medal. It has been estimated that 80 per cent of penicillin is now wasted for the following reasons: (1) It is used for diseases in which it is known to have no effect; (2) fever is often the only indication for its use; (3) dosage is often either too small or too interrupted, or too large or given longer than is needed; (4) oral therapy requires two to four times the amount needed for parenteral therapy, and (5) it is used as a prophylactic too often in the absence of evidence of its usefulness for this purpose. While these abuses are not in themselves serious except for occasional untoward effects, economic waste and their contribution to repeated recent shortages, a possible far more serious aspect must be considered. It has been predicted that the widespread use of penicillin will gradually induce penicillin-resistant bacteria to arise which after several years will cancel its curative effect. This has already occurred among certain hemolytic streptococci and gonococci as regards sulfonamide therapy and prophylaxis. Another seldom discussed problem of wide social implication is the moral effect of the knowledge that certain venereal diseases can be easily cured. It is also hoped that physicians will resist the commercial exploitation of penicillin under various proprietary names and in various unnecessary vehicles.

The greatest success of penicillin therapy has been attained in the treatment of infection caused by pneumococci, streptococci, staphylococci, gonococci and meningococci. It is of value in the treatment of early syphilis, but further study is needed before the eventual outcome can be judged. At present, parenteral, oral and topical routes of therapy are fairly well understood and are preferred. Until further experience has accrued, intrathecal therapy and the inhalation of nebulized penicillin must be regarded as in the experimental stage. It is now known that commercial penicillin is not a single substance but a mixture of at least four substances, called G, X, F and K. Since some are more active than others, intensive research is under way to provide a product containing constant amounts of the effective fractions.

Streptomycin has not given the good results at first expected from it. Although it is theoretically specific for typhoid and brucellosis, actual experience has been discouraging. It is of value in the treatment of patients with tularemia, with certain infections caused by Pfeiffer's bacilli, or with certain infections of the urinary tract, and to clear the bowel temporarily of streptomycin-sensitive bacteria. Studies of its effects on tuberculosis, plague and other diseases are not advanced enough to draw conclusions. Various strains of bacteria, even of those of a single species, vary greatly in their resistance to streptomycin, and in some instances sensitive strains develop resistance with great rapidity.

Further studies on the therapy of acute rheumatic fever casts doubt on the value of massive doses of salicylate drugs recently recommended. Large dosage often causes toxic effects and even fatal results without influencing the actual infection more than the dosages of 8 to 12 Gm. daily, as heretofore used. Evidence of infection may even develop during therapy. Symptomatic relief is the most that can be expected.

Many other new developments in the field of infectious diseases pertaining to aspects other than therapy are discussed elsewhere.[1] Progress in the treatment of arthritis, exotic diseases and in infections caused by viruses is discussed by other members of this panel.

GASTROENTEROLOGY

WALTER C. ALVAREZ, M.D.
Rochester, Minn.

Probably the most interesting question in the minds of gastroenterologists today is whether double vagotomy well above the cardia, with or without gastroenterostomy or partial gastric resection, constitutes the long looked-for perfect operation for peptic ulcer.

Whatever happens, the medical profession will long owe Lester Dragstedt a debt of gratitude for having given this operation a good trial. This required courage, because the results of cutting both vagus nerves in animals and one vagus nerve in man had not been encouraging to those who wished to use this procedure in the treatment of peptic ulcer.

In the last three years some two hundred double vagotomies have been performed, and in almost all cases so far reported the results have been encouraging. Usually the pain and discomfort have promptly stopped, and the ulcer has apparently healed. I have heard of only 1 case in which the pain continued unchanged, and it may be that in that case the nerves were not all cut. Apparently if only a few fibers are left—and they can easily be left—the results can be nil.

It is hard to say why the good results are obtained so promptly and consistently, because in a considerable percentage of cases the gastric acidity is not done away with and in some it has not even been altered. In other cases in which it was at first diminished it soon returned to normal or above. Apparently the particularly harmful night secretion is usually diminished in amount. In most cases the gastric glands continue to respond normally to stimulation by histamine.

It is hard to say why the pain goes so promptly. The fact that in a few cases the putting into the stomach of some 0.5 per cent solution of hydrochloric acid no longer caused pain suggested some diminution in sensitivity of the mucosa, but the fact that the blowing up of a balloon in the esophagus or stomach or duodenum still produced pain and the fact that an intestinal obstruction after vagotomy caused much pain showed, as was to be expected, that the sensory pathways had not been interrupted. After the operation hunger and nausea can still be felt and the gallbladder continues to function normally. The patients tend to gain in weight.

All this is most encouraging. The questions that most need answers are whether the operation is safe, whether there are any serious drawbacks or contraindications and whether the good results will be permanent.

The main difficulty encountered so far, as reported by a number of observers at the May meeting of the American Gastro-Enterologic Association, is the failure of the stomach to empty properly after the operation. A six hour retention of all food and even failures to empty in twenty-four hours are common. Because of this, surgical interns are sometimes kept busy washing out a patient's stomach, and in some cases the surgeon has felt compelled to operate again and perform gastroenterostomy. In some cases at reoperation a dilated paralytic segment of bowel has been found. As yet no drugs have been found which will relieve this stasis. Naturally, the patient often feels full, but the fact that he gains in weight shows that eventually the food goes through into the bowel. Most patients are troubled for a while by diarrhea, but in most cases it soon disappears. This symptom may be associated with distress in the lower part of the abdomen.

A big simplification in the technic of the operation was made by Dragstedt when he found that he could cut the cardia away from the diaphragmatic hiatus, pull down the esophagus, cut the vagi and then, after letting the esophagus slip back up, sew the edges of the hiatus close to the cardia again.

Certainly every one will watch the results of this new operation with great interest. Perhaps it does what is so much needed in cases of ulcer, and that is to interrupt pathways which carry to the upper part of the digestive tract harmful influences that arise in the brain.

Every war brings to the fore a new disease, and in World War II this was infectious hepatitis. It occurred in epidemics and caused much disability. It appears to be produced by two viruses which unfortunately are highly resistant to disinfecting agents. The period of incubation is remarkably long—in one type of case from twenty to thirty-five days, in another type from sixty to one hundred and twenty days. Partly as a result of this long period of incubation and partly because of the existence of carriers many men got the disease by means of a transfusion or even when a contaminated hypodermic needle was used. Some epidemics were caused by a water-borne virus. If only because of the frequency with which transfusions are now given, we physicians will probably long be plagued by epidemic hepatitis.

Perhaps for a while we shall do well to study the function of the liver in puzzling cases of indigestion and especially those in which there is much soreness and aching in the right upper quadrant of the abdomen.

The situation in regard to gastritis seems to be clarifying, and there is now less excitement about the superficial and atrophic types. Some authorities are pointing out that many of the minor changes seen in the mucosa may be transient and unimportant, like those seen in Alexis St. Martin and in Tom who was studied by Wolf and Wolff. The atrophic type probably often is not a gastritis in the sense that "itis" means inflammation.

ENDOCRINOLOGY

EDWARD H. RYNEARSON, M.D.
Rochester, Minn.

The best summary of the advances in endocrinology which I have seen is the booklet entitled "Exhibit on Endocrine Products." The booklet can be obtained by writing to the Council on Pharmacy and Chemistry of the American Medical Association. Dr. Austin Smith and Dr. Walton Van Winkle are to be commended for their fine work on this booklet, and particularly for their listing of all accepted brands of commercially available hormones. In this small booklet the authors were unable to go into much detail. Not every physician will agree with every statement; most physicians, however, will agree with the conservative point of view.

THYROID

Two of the recent advances pertain to the thyroid. One is the use of goitrogens, such as thiouracil and propylthiouracil, which were described by Astwood and VanderLaan and by Williams and others. The exhibit regarding the effect of goitrogens by Dr. Elmer Bartels, which has been awarded the silver medal, summarizes the present knowledge of these substances. The other advance pertains to the use of radioactive iodine. In a recent issue of The Journal of the American Medical Association, articles by Hertz and Roberts and Chapman and Evans and an editorial present up-to-date information on the use of radioactive iodine. These workers report results obtained from the use of radioactive iodine prepared in the laboratories of the Massachusetts Institute of Technology. Concurrently, studies have been carried out in California by Hamilton and Soley and their associates using material prepared in the cyclotron of the University of California by Lawrence. Reports involving patients have not been published by the Western group. It is far too early to define the uses and limitations of treatment with this substance. Whether it is a medical cure for hyperthyroidism cannot be stated at this time. What effect it will have on the parathyroid glands and what later effects, such as the development of myxedema or carcinoma, may be observed are not known.

PARATHYROID GLANDS

The medical profession continues to be indebted to Dr. Fuller Albright and his associates for its knowledge of hyperparathyroidism. The importance of methods for the earlier diagnosis of this condition have been emphasized recently by Keating and Cook. If physicians can diagnose hyperparathyroidism before serious damage is done to the kidneys, bones and other parts of the body, then, after successful operation, these patients may be saved from the devastating effects of this condition. No new methods of treatment of parathyroid insufficiency have been introduced.

ADRENAL CORTEX

The treatment of Addison's disease continues to be less than satisfactory. Commercial firms have made available extracts of the whole adrenal cortex and have provided a synthetic fraction, desoxycorticosterone acetate. These two types of substances have improved the prognosis of Addison's disease but what we, as physicians, most desire in treatment of this condition is better and more potent whole adrenal cortical extracts and other synthetic fractions. Desoxycorticosterone acetate has a definite effect on the retention of salt and water but does not constitute complete replacement therapy for Addison's disease. The present treatment for Addison's disease, especially treatment with whole adrenal extracts, is far too expensive for most patients.

Results of treatment of Cushing's syndrome, whether it is caused by a basophilic adenoma of the pituitary or by hyperplasia of the adrenal cortex, continue to be extremely discouraging. The somewhat comparable condition produced by a tumor of the adrenal cortex or by arrhenoblastoma of the ovary responds well to surgical treatment provided metastasis has not occurred.

ADRENAL MEDULLA

An important new advance is the use of histamine in the diagnosis of pheochromocytoma. Roth and Kvale have found that an injection of a given amount of histamine will produce an attack of paroxysmal hypertension if a tumor is present.

PANCREAS

The use of alloxan or of the diabetogenic hormone of the pituitary for production of diabetes in experimental animals has given scientists another opportunity to explore the etiology and pathology of diabetes.

ESTROGENS, ANDROGENS, PROGESTERONE AND PREGNENOLONE

The list of estrogens available for clinical use fills two pages of the booklet mentioned at the beginning of this summary. They certainly have helped many patients who need estrogenic therapy, but physicians have improperly used estrogens, as well as androgens, in many instances. The title of the paper by Dr. Willard Thompson, at this meeting, "The Uses and Abuses of Male Hormone," was indeed well chosen. Estrogens and androgens are of greatest use for treatment of patients whose conditions are caused by a lack of these hormones. Mention should be made of the use of estrogens in the treatment of carcinoma of the prostate and the use of androgens in treatment of inoperable carcinoma of the breast. The early enthusiasm regarding the use of progesterone is being supplanted by more cautious statements in the literature. A new steroid, pregnenolone, may prove important. Its uses have not been clearly defined, but Pincus, Hoagland and their associates have described its use in preventing fatigue. Unquestionably, these hormones are important, but results of their use need to be evaluated more carefully.

GONADOTROPINS

Physicians are in general agreement that cryptorchism will respond to the use of gonadotropins in certain cases. Competent observers agree that when gonadotropins are administered the testes will descend into the scrotum in those boys whose testes would enter the scrotum later if the injections were not given. Many of these observers think that effecting descent of the testes into the scrotum prior to puberty is of some advantage and also that gonadotropins make operation easier in case the descent is not complete with hormonal treatment. I believe that it is unfortunate that gonadotropins are being used in a large number of other poorly defined conditions. More unfortunately, too few clinical studies contain adequate observation of control groups. If investigators in the field of basic medical science are impressed with the importance of adequate control studies, it seems that it would be wise

clinicians also to make control studies of patients. New hormone fractions cannot be evaluated properly unless these studies are made.

PREPARATIONS OF THE ANTERIOR LOBE OF THE PITUITARY GLAND

I know that this audience joins in offering congratulations to Dr. Herbert Evans and his associates for receiving the gold medal for their exhibit on the fundamental aspects of the anterior lobe of the pituitary gland.

At this time, there is not generally accepted evidence that any commercially produced extract of this substance has proved of value in the treatment of human beings. Pure fractions of the anterior lobe of the pituitary gland have been produced which, in animals, have proved effective. It is to be hoped that in the future such extracts may be available for treatment of human beings. Physicians agree almost unanimously that products of the anterior lobe of the pituitary gland prepared for oral administration are totally worthless.

COMMENT

Finally, it does not seem out of place to comment that the best information regarding endocrinology is available in scientific journals, such as the *Journal of Endocrinology* and the *Journal of Clinical Endocrinology*. It is not unfair to state that pharmaceutic houses are primarily interested in the sale of their products and that statements appearing in their publications are not always accepted by members of the research departments of the same firms. It should be added that physicians should not be misled by overly enthusiastic writers for lay publications or by unscientific claims of pseudopharmaceutic firms. Nevertheless, members of the medical profession are greatly indebted to the reliable pharmaceutic firms for their aid.

CARDIOVASCULAR DISEASE

WILLIAM J. KERR, M.D.
San Francisco

Some of the most noteworthy advances in the treatment of cardiovascular disease have been made by surgeons in what was formerly considered a hopeless field —congenital heart disease. Patent ductus arteriosus, when attacked at an early age by surgeons of skill, has been removed as a later hazard to life from heart failure or infectious endarteritis. Coarctation of the aorta has likewise responded to skilful hands through resection of the narrow segment followed by end to end anastomosis. The condition of children with the tetralogy of Fallot and some other congenital lesions accompanied by cyanosis has been improved, at least temporarily, by anastomosing a branch of the aorta to the pulmonary artery. Although symptoms may be temporarily abolished, the fistulous tract may present a later hazard. Furthermore, the pulmonary stenosis is not corrected by this procedure. Better results might be achieved by a plastic operation on the pulmonary valve and conus at the site of the stenosis. During the war several surgeons have had unusual opportunities to treat patients in the younger age group with arteriovenous fistulas. The results have been notable. In civil life many patients with such lesions may be older, with more brittle vessels, so that there may be fewer successes.

SYMPATHECTOMY FOR HYPERTENSION

Recently interest has been shown in sympathectomy for hypertension. Many such operations have been performed by skilled surgeons, and in some quarters all comers are accepted for treatment. Surgeons still do not know how to select patients who may be expected to benefit by the procedure, which is a major operation with some undesirable after-effects. The percentage of beneficial results is about the same as after the use of other methods employed with equal enthusiasm and diligence. Hypertension by itself does not often give symptoms until the subject is aware of his high blood pressure, and he is generally relieved of his symptoms of anxiety after such operations or after any method of treatment carrying an impact of suggestion. One must raise the question whether sympathectomy is not another example of the mastery of technic over reason and whether it will not soon fall into discard along with sympathectomy and thyroidectomy for heart disease.

PROTRACTED EDEMA

Among the recent medical advances is the recognition of the great value of an extremely low sodium intake in the treatment of protracted edema. Whether fluids should be forced in addition may be open to question, but if left to their own devices such patients will take less fluid voluntarily and will not suffer from thirst as under former methods. The posture of the patient with dependent edema or anasarca is of great importance. It is better to put the edematous and orthopneic patient in a comfortable chair with support for the shoulder girdle than to force him to remain in a cramped position in bed. Soggy feet are better than soggy lungs.

CORONARY OCCLUSION

Anticoagulants are being recommended for patients with coronary occlusion. If they are to be used they should probably be instituted within the first forty-eight hours. At present Dicumarol (3,3′-methylene-bis-[4-hydroxycoumarin]) would appear to be the most suitable anticoagulant, but it should be used only under the most careful laboratory control. Thrombosis and pulmonary embolism from clots in peripheral veins may likewise be controlled by the proper use of anticoagulants. The wholesale ligation of veins, including on occasion the inferior vena cava, as a prophylactic measure, would not seem to be a reasonable procedure.

There has been an increasing appreciation of the value of intravenous administration of morphine in doses of ⅛ to ⅙ grain (8.1 to 10.8 mg.) for pain in coronary occlusion. I am convinced that the protracted pain is of major importance in causing the state of shock, which in itself may extend the zone of damage of the infarcted area. Perhaps more attention to treatment of shock by the usual or acceptable methods may be of additional value.

The treatment of angina pectoris by methods which promote the return of blood to the heart is at present the only rational approach to the problem. When the members of the medical profession understand how to use such methods many lives will be spared and many useful years will be added.

Purified glucosides of digitalis have all but eliminated the uncertain methods of standardization formerly in use.

RHEUMATIC FEVER

Salicylates have been employed in large doses recently in the treatment of rheumatic fever. The symptoms have been mitigated by this method, but convincing proof is lacking that the cardiac damage has been lessened. It may be worthy of note that salicylates were given in large doses thirty years ago in the Massachusetts General Hospital and other hospitals without apparently modifying the degree of cardiac involvement. The value of sulfonamide drugs in preventing recurrences of rheumatic fever is not determined, but they would appear to be useful when given continuously in small doses. The questions of sensitization to the drugs and fastness of organisms are not yet answered, but I should think that these risks should be taken in view of the dangers of repeated insults to the heart.

The medical profession is approaching a solution to the etiology of rheumatic fever, and when the constitutional factors are better understood one should expect to terminate an attack in being or to interrupt the process before the biologic trap has been sprung and after the organism (streptococcus) has baited it.

VIRUS DISEASES

EDWIN W. SCHULTZ, M.D.
Stanford University, Calif.

In contrast with recent advances in antibacterial therapy, specific measures are available for few virus diseases. This cannot be laid to lack of research in this field, since many potential agents have been tested for their possible antiviral activity. Probably the most important factor responsible for this situation is the distinctive host-parasite relationship in virus infections, which has added greatly to the problem of dealing with this group of infectious agents. In bacterial infections the relationship of the agent is primarily an intercellular one, with the parasite exposed not only to the antimicrobic substances which the host may build up but to agents artificially introduced into the blood or taken up by the blood from the digestive tract. In virus infections the relationship is intracellular, with the virus quite out of reach of potential therapeutic agents brought to the infected area. Moreover, the initial invasion may be extensive and involve many cells simultaneously, so that by the time symptoms of infection appear little opportunity remains to change the natural course of the disease. Agents the effects of which depend on a direct action on the virus could be effective only while the virus is on its way from one cell to another. Such a successive invasion of cells might conceivably be prominent enough in individual virus diseases to afford some opportunities for a direct attack, and one would expect opportunities to be greater in those diseases known to be associated with a viremia or a blood phase. It is known, of course, that the use of immune serum early in measles serves to modify its clinical course, but this is one of the few virus diseases in which the value of immune serum is generally recognized. Even here it must be given early in the disease to be effective. Theoretically, then, the chances of limiting a virus infection with antiviral agents would seem to be small and limited to the few opportunities which may exist of "picking off" the virus particles while they are in transit from one cell to another. This applies also to antibodies, since immune globulins are generally held to be much too large to enter tissue cells. This view is supported by the results of serum therapy in virus diseases in general.

However, while the prospects of ultimately finding specific therapeutic measures against individual virus diseases are not bright, there is some ground for continued optimism. It is possible, for example, to point to the effective use of chemotherapeutic agents in two or three virus diseases, in spite of this intracellular relationship. Favorable results have been obtained with the sulfonamide compounds in trachoma, inclusion blennorrhea and lymphogranuloma inguinale, while penicillin has recently been observed to exercise some therapeutic effect in experimental ornithosis and psittacosis. All the viruses associated with these diseases are large viruses, and morphologically distinctive, in that they are rickettsia-like. They are nevertheless intracellular in their relationship to the host. Rickettsias also are intracellular parasites. In spite of this, therapeutic effects have been obtained with penicillin in experimental murine typhus. Encouraging results have also been obtained with para-aminobenzoic acid in certain rickettsial infections. It would appear, therefore, that an intracellular relationship in itself does not wholly preclude a possible solution of the problem of how to reach virus already sheltered within infected cells.

It is possible that the true solution will have to be found in a way which does not involve direct action on the virus, but which involves indirect action by some means which will render the protoplasmic soil of normally susceptible cells unsuitable for the multiplication of a given virus. Poorly nourished animals have been observed to be less satisfactory for experimental work on certain virus diseases than well nourished ones. Thiamine deficiency has been observed to result in some increase in resistance to experimental poliomyelitis in mice. It is known that robust health cannot be counted on to afford added protection to a person who is naturally, or genetically, susceptible to a given virus infection. There is obviously something about his protoplasm which favors the implantation and multiplication of a given virus. Why his cells afford a protoplasmic soil suitable for the multiplication of a virus and the cells of another species contain a protoplasm which is barren for this same virus is a question which all physicians should like answered. The latter state might conceivably be created artificially, if the answer to this question were known.

There is another aspect to be considered in the treatment of virus diseases, namely, the control of secondary bacterial invasion. There are some virus diseases, such as smallpox and influenza, in which secondary bacterial invasion may add greatly to the weight of the infection. Against this contingency the sulfonamide drugs and the antibiotics are now available and can be drawn on when indicated. Timely immunization against influenza should in itself do much to reduce the incidence of secondary pneumonia, but whatever prediction may be justified along this line, there are now, in addition, these highly effective antibacterial agents with which to deal in this complication. Severe smallpox is not wholly a virus infection, but it is commonly associated with systemic invasion by pyogenic cocci. While there is not any specific measure against the virus itself, it should be possible to do something to combat the secondary bacterial invasion which may add greatly to the weight of a smallpox infection.

While little can be said regarding specific therapy in virus diseases, much could be said regarding recent advances in immunization against them. Because of the host-parasite relationships mentioned, virus diseases must be thought of much more in terms of prevention than of treatment. Many have yielded to immunization. Unlike most bacterial vaccines, viruses are, as a rule, good immunizing antigens. This does not mean that they always create increased resistance when injected as vaccines, especially when injected in an inactive form, since a well defined increase in resistance may depend on more than the mere presence of antibodies in the blood. To induce a definite immunity against certain virus diseases it is obviously necessary to induce a modified infection with living virus, as in vaccination against smallpox. These infections apparently give rise to some protoplasmic change within normally susceptible cells, as well as to formation of antibodies, the former being the more important factor in acquired resistance. Vaccination against yellow fever is carried out with a living modified virus. In general, however, the quest has been for nonviable vaccines of sufficient concentration and immunizing potency to stimulate a good humoral immunity, if nothing more. Such vaccines are possibly more likely to prove effective against infections in which a viremia, or blood phase, precedes the cellular invasion. Among the virus diseases against which active immunity can be established with suspensions of inactivated virus are influenza, equine encephalomyelitis and possibly epidemic encephalitis.

In this brief survey it is necessary to exclude all reference to the many advances which have been made outside of the field of specific therapy and prophylaxis, such as in the electron microscopy of viruses and their cultivation, purification and chemical analyses, and in variations in viruses. It is in these fields that some of the greatest advances have been made. Out of these may eventually come some way of effectively dealing with virus diseases at the bedside.

ARTHRITIS

PHILIP S. HENCH, M.D.
Rochester, Minn.

There are actually about two hundred forms of "rheumatism," including about one hundred different types of arthritis. But approximately 85 per cent of "rheumatic patients" suffer from one of seven common conditions: rheumatoid arthritis, osteoarthritis, the polyarthritis of rheumatic fever, periarticular or intramuscular fibrositis, psychogenic rheumatism, gout or gonorrheal arthritis. This discussion will be confined to five of these common forms.

RHEUMATOID ARTHRITIS

Penicillin.—Because of a supposed relationship between hemolytic streptococci and rheumatoid arthritis it was hoped that penicillin might be of value. This hope has not been realized. Large doses of penicillin have been given intramuscularly daily for from three to six weeks, or orally daily for from one to six months. No significant benefits were noted.

Streptomycin.—Streptomycin has been of no value in the few cases in which its use has been reported.

Neostigmine (Prostigmine); Physostigmine.—Chiefly to relieve painful spasms of the muscles in rheumatoid arthritis neostigmine bromide, orally or subcutaneously, was recently recommended. Later physostigmine salicylate, subcutaneously, was considered superior to neostigmine. The early favorable reports were not sufficiently critical. At the recent meeting of the American Rheumatism Association several experienced rheumatologists expressed their disappointment with this type of treatment and their belief that neostigmine was of little or no value in rheumatoid arthritis. Trommer's point of view was that neostigmine, given orally, is not of value and that neostigmine and physostigmine, given subcutaneously, can be regarded as adjuvants only. He stated, "When articular inflammation has subsided and deformity is due to muscle spasm then prostigmine may help." Recent experiences with soldiers with rheumatoid arthritis at one of the Army's rheumatism centers led Balboni, Hollander and Kydd to conclude that "prostigmine induces no significant relaxation of muscle spasm in rheumatoid arthritis. The slight variations in range of articular motion can be accounted for by the daily variations caused by changes in weather, fatigue or other influences which so commonly make the rheumatic patient better on some days and worse on others. A potent drug such as prostigmine should yield much more definite benefit than we have observed in order to justify its continued use in rheumatoid arthritis."

Antireticular Cytotoxic Serum.—Claims have been made by Bogomoletz and Strazhesko that "rheumatism" is one of the conditions relieved by injection of minute quantities of serum of animals into patients. The serum is generally obtained from rabbits immunized against human reticuloendothelial tissue cells. It is not clear what type or types of "rheumatism" were treated. According to one report Bogomoletz claimed that "in cases of acute arthritis it is a quick and certain cure, but when there is endocarditis application of the serum has a bad effect."

The serum was recently investigated for the British Empire Rheumatism Council by Bach. Results in various rheumatic diseases, including rheumatoid arthritis, were essentially negative. The Empire Rheumatism Council does not recommend its use. When informed of Bach's work Bogomoletz is said to have stated that "the serum is suitable for the cure of rheumatism only in the acute phase of the illness." According to Bach, Strazhesko, a colleague of Bogomoletz, has stated that "in chronic rheumatism (chronic arthritis and endocarditis) the serum should not be used."

Freyberg has completed a preliminary (unpublished) investigation of its use in about 30 cases of rheumatoid arthritis and spondylitis. Results to date have been disappointing. The serum is now being prepared in this country (Wyeth, Incorporated) and is available for further clinical trials.

Vitamins.—Recent studies have led to the following conclusion: "There seems to be no direct indication for the use of vitamin A, vitamin B complex (thiamine hydrochloride, niacin, riboflavin), vitamins C, E, or K in the relief of symptoms of chronic arthritis" (Traeger). I subscribe to this conclusion.

Although a few physicians still consider the use of concentrated doses of vitamin D, including ertron, of some value, the majority of experienced rheumatologists regard it as essentially useless. In some cases a slow moderate improvement (generally only subjective) may be noted, but the results are mainly disappointing. Severe, even fatal toxic reactions may occur; hence some have called the use of large doses of vitamin D for arthritis "a dangerous practice which may do the patient harm."

Gold Salts.—Although chrysotherapy for rheumatoid arthritis has been employed for eighteen years, its exact value is still undetermined. At the recent meeting of the American Rheumatism Association the opinions

---

From the Division of Medicine, Mayo Clinic.

expressed concerning chrysotherapy were diverse. The three chief drawbacks to this therapy are as follows: (1) Notable results are obtained in only about 20 to 35 per cent of cases; (2) relapses are common even when good results have been obtained, and (3) toxic reactions are frequent, occasionally serious. Because of these limitations certain physicians have abandoned its use. Other physicians employ gold compounds only when other measures have failed. But many experienced, careful rheumatologists maintain their conviction that chrysotherapy is the best single remedy for rheumatoid arthritis, and they urge that it be instituted as early as possible, preferably within the first two years of disease, rather than late after the disease has become more or less irreversible. According to Cecil, "It is a pernicious doctrine to advocate the use of gold only after everything else has been tried."

Toxic Reactions: Significant, but not necessarily serious, toxic reactions occur in approximately 25 to 30 per cent of cases in which chrysotherapy is employed. Serious toxic reactions occur in about 5 per cent (or less). Fatal toxic reactions occur in from 0.25 to 0.45 per cent of cases. Thus, in three recently reported series deaths occurred in 2 of 460 cases (Ragan and Tyson), in 2 of 500 cases (Boots) and in 2 of 800 or more cases (Cecil). Of recent years the incidence of fatal reactions has been reduced materially (from 3 per cent in 1935). Further experience should lower it still more.

Toxic reactions do not bear a constant relationship to the doses of gold used and may appear early or late during treatment. According to some authorities, they are related more to the duration of the disease than to the amount of gold given: reactions occurred twice as often in cases of ten or more years' duration as in earlier cases. Cutaneous reactions may be mild, or severe as in the exfoliative type. There is no way to detect impending dermatitis: eosinophilia does not necessarily precede it or indicate, when it is present, that dermatitis is impending. Serious reactions which have been fatal include thrombopenic purpura, aplastic anemia, acute glomerular nephritis, toxic hepatitis, agranulocytosis and acute enterocolitis. Agranulocytosis can now be controlled if penicillin is given promptly. According to Cecil, vitamin K and transfusions may be inadequate to control hemorrhagic purpura resulting from gold; in his hands splenectomy has been a lifesaving measure. There is no known method of preventing toxic reactions, but their early discovery and control demand constant vigilance and frequent (perhaps weekly) examination of the patient's skin, blood and urine. "When these rules are faithfully followed, gold therapy can be used with a fair degree of safety" (Cecil).

Results: Considerable benefit in the majority of cases was reported by Cecil. Ragan and Tyson, in a follow-up study of 142 cases for three or four years, noted "marked objective improvement" in 35 per cent (50 cases); a "five year cure" was obtained in 9 (6 per cent) of the 142 cases. But the term "cure" is less appropriate than "complete remission."

Other American rheumatologists who have been less impressed by chrysotherapy have observed notable improvement in only 20 per cent and "arrests" in only 15 per cent of their cases. They observed great improvement only rarely and emphasized that those who report the best results are treating early rheumatoid arthritis; in early cases many remedies much less toxic than gold reputedly give notable results. Steinbrocker stated that too often advocates of chrysotherapy report "wishful statistics" and lump together patients "cured or improved" to make an impressive showing.

Relapses: When injections of gold are given by the course and then discontinued, the rate of relapse is high: from 50 to 80 per cent. Relapses often occur because of the necessity of the patient to return to fairly strenuous physical work. In 75 per cent of the cases of Ragan and Tyson (in which the course method was used) relapses occurred within one to fifty-eight months after injections were stopped. Although patients may receive further benefit from more gold, the results from a second course are not likely to be as good as from the first. Relapses were noted to occur just as often among early as among late cases.

Newer Plan of Dosage: Because gold salts accumulate notably in bodily tissues when weekly doses of 100 mg. are given, and in order to reduce toxicity, the current trend is to use smaller doses than formerly, generally with a maximal weekly dose of 50 mg. (25 mg. in cases of mild disease). One or two weekly doses of 10 mg. each are given, then one or two of 25 mg., and thereafter 50 mg. weekly. To reduce the tendency for relapses many rheumatologists no longer give courses of treatment and stop treatment after 1 or 1.5 Gm. has been given but continue weekly doses of 50 mg. until the patient's symptoms are relieved and the sedimentation rate returns to normal. Thereafter "maintenance doses" are given indefinitely, 50 mg. once every two, later every three or four weeks. If no definite relief is noted after five or six months of treatment or after about 2 Gm. has been given, further chrysotherapy is generally useless.

Conclusions Regarding Chrysotherapy: Obviously chrysotherapy is "still on trial," but its protagonists contend that arsenotherapy for syphilis was likewise on trial for several years until satisfactory methods of administration were finally developed. Some neutral observers have stated that the advocates of chrysotherapy are waging an uphill, losing fight. Bauer, who has concluded that his results from older methods of treatment are as good or better than from gold, expects the use of gold salts to be abandoned in the not too distant future even though no striking new substitute is forthcoming. Advocates of chrysotherapy admit that this remedy should not be relied on exclusively and that other general measures (rest, removal of foci, nutritious diet, physical therapy) should supplement it. In view of its hazards chrysotherapy should be used only by physicians familiar with, or willing to familiarize themselves with, the details required for adequate control, by physicians with hospital and laboratory facilities and by those willing to carry out repeatedly the necessary clinical and laboratory precautions. In view of the serious potentialities of rheumatoid arthritis, I believe that chrysotherapy is justified whenever rheumatoid arthritis has lasted more than a few months and shows evidences of being progressive, provided that the patient understands and is willing to share the risks.

RHEUMATOID SPONDYLITIS

Roentgen Therapy.—Although roentgen therapy in cases of peripheral rheumatoid arthritis has been generally disappointing, it has been reputedly of considerable value in cases of rheumatoid (ankylosing) spondylitis. Of 52 patients treated by Smyth, Freyberg and Lampe in 1941, notable subjective improvement was obtained in 72 per cent and impressive objective improvement in 50 per cent. To rule out a psychic effect other patients were given "placebo therapy" (they were placed on the roentgen therapy table; a lead screen was used to block the roentgen rays); no patient was notably improved.

The more recent experiences of Freyberg have confirmed these earlier results. This work has recently been further confirmed and extended by Smith, Boland, Shebesta and Hench, who treated 25 spondylitic soldiers with roentgen therapy alone, 25 with placebo therapy alone in the manner described (lead screen being used) and 25 with deep breathing and postural exercises alone. The patients were observed in an army hospital for at least one hundred and eighty days. Of those who received roentgen therapy subjective improvement was moderate in 56 per cent and pronounced in 36 per cent (total 92); objective improvement was moderate in 60 per cent and pronounced in 8 per cent (total 68). Of those given psychotherapy, who went through the ritual as for roentgen therapy but received no radiation, subjective improvement was moderate in 28 per cent and pronounced in 9 per cent (total 37); objective improvement was moderate in 8 per cent, pronounced in none. Of those given breathing and postural exercise alone subjective improvement was moderate in 40 per cent and pronounced in 8 per cent (total 48); objective improvement was moderate in 32 per cent and pronounced in 8 per cent (total 40). These results are notably in favor of roentgen therapy. Thereafter all patients received whatever treatment they had previously missed. The combined program of therapy was superior to any one alone.

OSTEOARTHRITIS

Although cup arthroplasties have been performed frequently on osteoarthritic hips since Smith-Petersen developed the procedure in 1939, studies on end results have been few. Recently reported were the results obtained at the Mayo Clinic in a series of 91 cases, 27 of which were cases of osteoarthritis, sometimes of the primary (idiopathic, senile) type, but generally of the type secondary to congenital anomalies, Legg-Perthes' disease, and so forth.

Results eight months to five years after operation in these 27 cases were as follows: In 15 per cent results were very good: The patient was able to walk without support and had good motion of the hip with no noticeable limp or pain. In 30 per cent results were good: pain was absent or minimal and the patient was able to walk well not only on the level but up and down stairs, although at times a cane was required. In the remaining 55 per cent, results were only fair or poor. Results were better among men than among women. Vitallium cups were superior to lucite cups.

Indications for Operation.—According to Ghormley cup arthroplasty is recommended, not for hips that are merely painful, but in cases in which pain is associated with considerable limitation of motion. It is not recommended for patients more than 60 years of age.

RHEUMATIC FEVER

Salicylates: Oral Versus Intravenous Administration.—Three years ago Coburn recommended that salicylates be given in large doses intravenously rather than orally and claimed that thereby the duration of the acute febrile polyarthritis and other features of acute rheumatic fever were shortened and the incidence of valvular heart disease was notably reduced. In the main this work has not been confirmed. Several recent reports have indicated that in general the intravenous administration of salicylates has no superiority over the oral administration. No differences were noted in the time necessary for articular pains to disappear or for sedimentation rates to become normal, in the incidence of polycyclic attacks, in the tendency for preexisting cardiac damage to progress or in the development of new cardiac involvement. Serious toxic, even fatal, reactions have occasionally resulted from such therapy.

Sulfonamide Prophylaxis.—The prolonged administration daily of sulfonamide compounds to patients, particularly children, who have previously had rheumatic fever has notably reduced the incidence of subsequent rheumatic attacks as well as the death rate from rheumatic carditis. Rosenberg and I recently summarized the seventeen studies of this form of treatment so far reported from ten different clinics, covering an experience of ten years. Among the rheumatic patients protected by sulfonamide compounds for one thousand and thirty-seven seasons, only 22 acute rheumatic exacerbations occurred, an incidence of 2.2 per cent, and only 3 patients died from rheumatic fever. But among the rheumatic patients who did not receive sulfonamide compounds during one thousand three hundred and forty seasons, there were six times as many recurrences (183 acute attacks, an incidence of 13.7 per cent) and almost twice as many deaths (5 deaths to date) as among those who received sulfonamide compounds for prophylaxis. Hence such prophylaxis appears to represent a really important medical advance. Toxic reactions were generally mild; the risks inherent in such chemoprophylaxis were considerably less than those from the disease not so treated.

GONORRHEAL ARTHRITIS

Falling Incidence.—Gonorrheal arthritis seems to be disappearing. Prior to the introduction of sulfonamide compounds it complicated 2 to 5 per cent of cases of gonorrhea. But during the war the incidence of gonorrheal arthritis among certain groups of soldiers with gonorrhea was only 0.1 to 0.3 per cent. Listed annually in the *Quarterly Cumulative Index Medicus* between 1930 and 1940 were an average of thirty-four articles on gonorrheal arthritis; in the past five years an average of only eight articles thereon has been listed annually. The incidence of gonorrheal arthritis per hundred thousand admissions to the Mayo Clinic has fallen from 45 in 1937 to 2 in 1945. This falling incidence constitutes one of the triumphs of chemotherapy, primarily with sulfonamide compounds. In view of this success the prompt recognition of gonorrheal arthritis is all the more important, because if it is treated promptly it is generally cured quickly and dramatically, whereas unrecognized gonorrheal arthritis can damage a joint seriously in a fairly short time.

Current Ineffectiveness of Sulfonamide Compounds.—Until recently sulfonamide compounds were effective against gonorrhea and gonorrheal arthritis in a high percentage of cases, but the sulfonamide-susceptible strains of gonococci have now largely been killed off in the United States, leaving mostly the sulfonamide-resistant strains to be combated. Hence the incidence of failures after sulfonamide therapy of gonorrhea has gradually risen from about 15 to 35 per cent; some say to as high as 80 per cent in certain regions of the country. Therefore penicillin has almost completely replaced sulfonamide compounds in the treatment of gonorrhea and gonorrheal arthritis.

Penicillin for Gonorrheal Arthritis.—Penicillin has been outstandingly successful in the treatment of gonorrhea because, of all the organisms susceptible thereto, the gonococcus is the most sensitive. Recently the War Department announced that of 11,000 soldiers who had gonorrhea 96 per cent were cured by penicillin alone; the remaining 4 per cent were generally cured by penicillin combined with sulfathiazole. Although some workers report cures in only 86 to 92 per cent of their cases, according to Keefer and Moore penicillin alone will cure genital gonorrhea in about 98 per cent of cases. One would expect, therefore, that penicillin should be about equally effective against articular gonorrhea. Early experiences seemed to justify this expectation, and in most of the reported cases of gonorrheal arthritis treated with penicillin in 1943 and 1944 cure was achieved quickly. But in the fall of 1944, certain failures with penicillin given for gonorrheal arthritis were reported.

Results from Penicillin.—I have been able to find, briefly mentioned in the literature on penicillin (1943 to 1946 inclusive), a total of only 82 cases of gonorrheal arthritis treated with penicillin. Of these 82 cases only 20 were of proved gonorrheal arthritis—that is, cases in which gonococci had been recovered from synovial exudate. The remaining 62 cases must be classified as presumptive gonorrheal arthritis. In most of these no articular cultures had been made; in a few, cultures of synovial fluid had been made but were negative. Practically none of the cases were described in any detail whatever. They were merely spoken of as "gonorrheal arthritis" or "acute gonorrheal arthritis," "arthritis with gonorrhea," "subacute arthritis with gonorrheal urethritis" or "complicating arthritis."

Assuming for the moment that all 82 cases were actually cases of gonorrheal arthritis, results with penicillin can be summarized briefly. There were 18 cases of proved, and 59 of presumptive, acute gonorrheal arthritis and 2 of proved and 3 of presumptive "chronic gonorrheal arthritis."

In 11 (60 per cent) of the 18 proved cases of acute gonorrheal arthritis cure was obtained. In 1 case penicillin, given intravenously, was promptly effective. In 2 other cases only partial improvement resulted from the intramuscular or intravenous administration of 160,000 units of penicillin given within forty-eight to sixty hours, whereupon in each case penicillin was given intra-articularly once a day for three days (a total of 8,700 and 10,000 units respectively) with prompt cures. Hirsh, Feffer and Dowling gave penicillin, generally intramuscularly, to 15 patients with proved acute gonorrheal arthritis: Seven patients who received "short courses" of penicillin in doses totaling 50,000 to 2,400,000 units within about three days were not cured. But prompt cures were obtained by 8 patients who were given larger total doses, 925,000 to 2,000,000 units within five to ten days.

Of the 59 patients with presumptive acute gonorrheal arthritis 34 (58 per cent) were cured, and 25 (42 per cent) were not cured. Of the 5 patients who had chronic gonorrheal arthritis, 1 patient who had presumptive arthritis of more than three years' duration was reported as being promptly cured (20 per cent); the 2 patients who had proved gonorrheal arthritis of three and six months' duration, treated with "short courses," and 2 patients who had presumptive chronic gonorrheal arthritis (no data given) were not cured (80 per cent).

Of the 77 cases of acute gonorrheal arthritis, proved or presumptive, cure resulted from use of penicillin in 45 (58 per cent) and was not achieved in 32 (42 per cent). Of all the 82 cases, acute or chronic, proved or presumptive, cure was obtained in 46 (56 per cent) and was not obtained in 36 (44 per cent) with penicillin. Results for the patients cured were described as "dramatic," "unequivocal within forty-eight hours," "striking," "excellent," "immediate," "complete and rapid within a few days."

Reasons for Failure of Penicillin.—If penicillin cures genital gonorrhea in 90 to 98 per cent of all cases, the question arises, Why does it cure gonorrheal arthritis in only about 58 per cent of cases? Why are not the articular complications, especially the acute ones, as amenable to cure as the other complications of gonorrhea, most of which respond readily if sufficient penicillin is given? Several reasons have been or can be advanced as possible causes for these failures: (1) the use of inadequate amounts of penicillin; (2) the supposed relative impermeability of the synovial membrane to penicillin, given parenterally; (3) the possibility that penicillin-resistant strains of gonococci are being encountered; (4) tardiness in instituting treatment; (5) the use of relatively impotent preparations of penicillin, and (6) errors in diagnosis.

1. Inadequate Dosage: The total dosages of penicillin used to treat most of the patients who were not cured were often not clearly stated, but they were usually between 60,000 and 100,000 Oxford units, rarely more, given as a rule intramuscularly. Hence some of the 36 failures (in 32 cases of acute and in 4 of chronic disease) admittedly resulted from the use of doses which are now known to be inadequate in some cases. With the present availability of penicillin, no future failures should be properly attributed to inadequate doses.

2. Concentration of Penicillin in Synovial Fluid: Early workers recognized that when penicillin was given intramuscularly or intravenously some of it appeared in synovial fluid. Herrell and his associates found only half as much penicillin in synovial fluid as in blood serum. Others noted that when penicillin was injected intra-articularly its absorption into the blood stream was tardy. For these reasons the impression arose that the synovial membranes are relatively impermeable to penicillin. Hence certain failures in the use of penicillin for gonorrheal arthritis have been explained by the curious notion that penicillin, given intramuscularly or intravenously, does not get into the articular cavity in sufficient concentrations to cure the gonorrheal arthritis.

As a matter of fact, Herrell noted excellent res[illegible]; despite the relatively lower concentrations of penicillin in synovial fluid in his cases, and more recently Balboni, Shapiro and Kydd, using a different method of assay, noted that penicillin, given intramuscularly in doses of 25,000 and 40,000 units every three hours, penetrated rapidly into synovial fluid and attained levels comparable with those in blood serum. Furthermore, maximal antibacterial quantities of penicillin persisted longer in articular fluid than in blood serum.

But even if such is not the case and the concentrations of penicillin in synovial fluid are considerably lower than those in blood serum, this still is an inadequate reason for failure, because gonorrheal arthritis is not a disease of the articular *cavity*. It is a disease of the synovial and periarticular tissues. Since these tissues are highly vascular, even more so when inflamed, there is no reason to suppose that penicillin entering the vessels of the articular tissues should not reach the infected regions.

It might be suggested that in the presence of inflammation synovial blood vessels and membranes are less permeable to penicillin than under normal circumstances. But this argument is not valid, either, because penicillin appears to permeate acutely inflamed membranes somewhat more readily than normal membranes; at least such is the case regarding the spinal membranes. The studies of Balboni and his colleagues were made in the presence of inflamed synovial membranes in rheumatoid arthritis.

3. Penicillin-Resistant Gonococci: Careful analysis of the failures of penicillin in the treatment of gonorrhea have been made by many investigators, but to date no naturally penicillin-fast strain of gonococcus has been encountered, nor has penicillin fastness developed under treatment. Although certain bacteria have been made resistant to penicillin in the test tube, development of clinical resistance has not become a problem. Such an eventuality may be prevented, in part, by the administration of adequate and not minimal doses of penicillin.

4. Tardiness in Treatment: In several cases gonorrheal arthritis had previously been treated unsuccessfully with sulfonamide compounds before treatment with penicillin; hence, there was some delay in administering penicillin. Because of the limited clinical data given it is impossible to say to what extent, if any, such tardiness contributed to the 36 failures. When gonorrheal arthritis is treated adequately within the first two or three weeks of the disease, a cure with complete functional restitution usually occurs. But, if the disease is allowed to continue untreated or inadequately treated for several weeks, irreparable articular destruction may occur, so that even though penicillin stops the active inflammation and cures the arthritis, complete functional recovery does not result. However, Suchet's patient who had presumptive chronic gonorrheal arthritis for three and a half years was reported cured with only minor articular residues when penicillin was finally available and given. (I find it difficult to accept this as a bona fide case of chronic gonorrheal arthritis.)

Delay in the use of penicillin need no longer be due to lack of supply.

5. Ineffective Penicillin: Commercial penicillin consists of varying amounts of one or more of the five known fractions F, G, X, K and dihydro F. Penicillin F and G are equally effective against gonococci; penicillin X may be several times more effective than F or G. But penicillin K has been found to be relatively ineffective, as it is rapidly destroyed or eliminated from the body and does not provide therapeutic levels in bodily fluids. For a few months in 1945 commercial penicillin may have had relatively less G and more K than previously. It is possible that some failures in the treatment of gonorrhea and gonorrheal arthritis may be thus explained. But ineffective penicillin cannot well be blamed for future failures, as the commercial preparations now available contain a preponderance of potent penicillin G. Even so, to insure against possible failure the National Research Council has recently recommended the use of increased doses of penicillin.

6. Errors in Diagnosis: In my opinion, the most common cause of past and future failures of treatment of gonorrheal arthritis with penicillin has probably been and will be an error in diagnosis. Experience at an Army rheumatism center revealed that most cases of so-called gonorrheal arthritis resistant to penicillin were not gonorrheal arthritis at all but were cases of rheumatoid arthritis in men who happened to have gonorrhea or of rheumatoid arthritis precipitated, reactivated or aggravated by genital (not articular) gonorrhea. In all likelihood some of the 36 failures reported to date were not in cases of gonorrheal arthritis. The 4 failures of Sternberg and Turner were listed as "articular involvement associated with a persistent gonococcic urethritis; presumably the joint lesions were gonococcic in origin." The 6 failures of Thompson were classified as so-called gonorrheal arthritis in which cultures of articular fluid were "never positive at any stage of the disease." Without knowing the clinical features of such cases I cannot judge whether they represented bona fide gonorrheal arthritis with negative articular cultures (as occurs in about 65 per cent of cases) or whether they represented nongonorrheal arthritis in patients with gonorrhea.

It is not sufficiently understood that acute genital gonorrhea is just one more acute infection which, like tonsillitis, influenza, scarlet fever, septic sore throat, and so forth, can act as a trigger mechanism for the production of rheumatoid arthritis. Acute gonorrhea can provoke the first appearance of rheumatoid arthritis, reactivate previously active but currently quiescent rheumatoid arthritis, or aggravate notably a coexistent rheumatoid arthritis. To the Army's rheumatism center were sent many patients with supposed gonorrheal arthritis resistant to sulfonamide compounds or penicillin or both who on further study proved to have rheumatoid arthritis precipitated or aggravated by acute gonorrhea. This was demonstrated by the completely negative reactions to therapeutic tests with high doses of penicillin, new articular sites often becoming affected during such treatment, by the subsequent course of the disease, the slow development of symmetric fusiform polyarthritis as characteristic of rheumatoid arthritis and in some cases by articular biopsies.

In the light of these facts, physicians should review the characteristic features and the criteria for a diagnosis of gonorrheal arthritis, proved or presumptive. Before classifying any case as one of penicillin-resistant gonorrheal arthritis one should review carefully the past articular history and the clinical features of any patient with supposed gonorrheal arthritis who does not respond promptly and satisfactorily to treatment. There is evidence to suggest that "postgonorrheal rheumatoid arthritis" is now more common than gonorrheal arthritis.

Treatment.—The control of gonorrheal arthritis resolves itself therefore into two problems: (1) accurate diagnosis and (2) the early administration of sufficient amounts of potent penicillin to provide antibacterial concentrations in affected articular tissues. At times the first problem may be more difficult than the second.

In doubtful cases, the patient should be given the benefit of a full therapeutic test.

When arthritis is a complication of gonorrhea, the use of Romansky's treatment with a single injection of penicillin in beeswax and peanut oil is probably inadequate. Penicillin should be given intramuscularly, 25,000 to 30,000 units every three hours (200,000 to 240,000 units daily) for from seven to ten days. If, within the first three or four days of such treatment, there is no definite improvement, intra-articular injections of penicillin of at least 10,000 to 20,000 units should be made once daily for three days if the affected joints are large enough to be so treated. If the patient's arthritis is not cured or unequivocally and notably improved within seven to ten days, the case and its diagnosis should be reviewed thoroughly.

SUMMARY AND CONCLUSIONS

A review of recent literature has been made for this discussion on arthritis.

In cases of rheumatoid arthritis no significant results have been obtained from penicillin, neostigmine (prostigmine), physostigmine or concentrated vitamins, including ertron. Preliminary results from use of streptomycin and from Bogomoletz's antireticular cytotoxic serum have been essentially negative; further clinical trials may be justified. Chrysotherapy is still on trial. Many experienced rheumatologists continue to regard it as the best single treatment now available and believe that, despite the risk of occasional serious toxic reactions, its use is justified in cases of progressive rheumatoid arthritis.

For rheumatoid spondylitis roentgen therapy appears to be the remedy of choice but should be combined with postural and deep breathing exercises.

In cases of osteoarthritis of the hips, arthroplasty and the use of vitallium cups after the method of Smith-Petersen have given satisfactory results in 45 per cent of cases, but patients must be carefully selected for the procedure.

For patients with rheumatic fever, salicylates given intravenously rather than orally have *not* been proved to be of superior value. Sulfonamide prophylaxis, the prolonged daily administration of sulfonamide compounds to patients who have had rheumatic fever, has notably reduced the incidence of subsequent rheumatic attacks as well as the death rate from rheumatic carditis. Rheumatic patients not protected in this manner apparently have about six times more chances of developing acute recurrent exacerbation than patients not so treated.

Gonorrheal arthritis, despite certain reports to the contrary, is generally cured promptly when enough penicillin is given. Failures have apparently resulted chiefly from inadequate dosages and perhaps also from errors in diagnosis which led to the treatment of patients with genital gonorrhea whose associated arthritis was nongonorrheal. It should be emphasized that rheumatoid arthritis can be precipitated, reactivated or aggravated by acute gonorrhea, just one more infection which, like influenza, tonsillitis, and so forth, can act as a trigger mechanism. At one of the Army's rheumatism centers cases of postgonorrheal rheumatoid arthritis were more common than cases of gonorrheal arthritis. Penicillin will cure the genital gonorrheal but not the associated or coincidental rheumatoid arthritis.

PANEL DISCUSSION

STERNAL PUNCTURE

QUESTION: Dr. Sturgis, please evaluate the diagnostic importance of sternal puncture.

DR. C. C. STURGIS, Ann Arbor, Mich.: Sternal puncture will confirm the diagnosis of blood disorder about two thirds of the times it is employed. It is therefore of great value from a confirmatory standpoint. It presents a specific picture in about 16 to 17 per cent of all cases of blood dyscrasias. These are multiple myeloma, Addison's pernicious anemia and allied macrocytic anemias, agranulocytosis and certain parasitic diseases such as leishmaniasis and malaria. There are two points to make: First, positive evidence is much more important than negative, and, second, although it is an easy thing to aspirate a drop or two of sternal marrow from the body of the sternum, it takes an expert with experience to interpret the results. Poorly interpreted, it does more harm than good.

SPLENECTOMY

QUESTION: What blood disorders are benefited by splenectomy?

DR. STURGIS: I believe there are only two, possibly three. The hemolytic anemias, either the chronic congenital hemolytic anemias or the acquired, which we are seeing more cases of, for some reason, are both benefited by splenectomy. Splenectomy should be considered in every instance in which these diagnoses have been established. The other condition in which it is undoubtedly of benefit is in idiopathic thrombocytopenic purpura. You should be sure of the diagnosis, of course, in both of these conditions. The third possible disease is Banti's syndrome, so called. I myself, do not think splenectomy is of value there, but some think it is.

HODGKIN'S DISEASE

QUESTION: Are platelets actually increased in Hodgkin's disease?

DR. STURGIS: The platelets may be increased in Hodgkin's disease, but in the terminal state certainly there is a leukopenia with thrombocytopenic purpura.

HEMOGLOBIN ESTIMATION

QUESTION: What is the most satisfactory clinical method of hemoglobin estimation?

DR. STURGIS: First, I believe that you should employ the method where the maximum depth of color is reached *instantly*. That can be done by putting the blood in an alkaline solution, ammonium hydroxide, and oxyhemoglobin is instantly formed. Second is a suitable colorimeter. The photoelectric colorimeter is being perfected; it is less expensive, and it can be used by the practitioner. I think the oxyhemoglobin method, which is described in any modern textbook on clinical pathology, and the photoelectric colorimeter method are the best.

BLOOD DYSCRASIAS

QUESTION: What are the most common blood dyscrasias encountered by any physician in the United States?

DR. STURGIS: I believe I can answer that, at least for the vicinity of Ann Arbor. We did 25,000 routine hemoglobin estimations on patients in the outpatient and inpatient services of University Hospital, and 12.5 per cent had anemias of clinical significance. Forty-one per cent of these anemias were of the iron deficiency type—that is important—due to hemorrhage, usually, and hemorrhage from the gastrointestinal tract or the uterus in the case of women. This is an important type of anemia, because it is the most common and yields most readily in most instances to large doses of iron. A close second in frequency was anemia associated with chronic infection, infection of the urinary tract, of the pelvis, chronic infection of the lung, osteomyelitis or any other type of infection. This is a moderate anemia. It is very common. There are only two therapeutic agents of value: one something to combat the infection, such as penicillin and blood transfusion. The anemia of this type is usually mild. The 20 per cent that are left were made up of pernicious anemia, aplastic anemia, hemolytic anemias, and so forth.

LEUKEMIA

QUESTION: What is the dosage of radioactive phosphorus in treating leukemias?

DR. STURGIS: In treating leukemias we give 6 millicuries orally once a week for three or four doses. There is an individual variation, however, in the dosage. We treat until the white blood cell count is about 40,000. It usually takes two to four doses of 6 millicuries each.

ULCERATIVE COLITIS

QUESTION: Dr. Alvarez, what's new in acute ulcerative colitis?

DR. WALTER C. ALVAREZ, Rochester, Minn.: Sulfathalidine is the drug I have heard most from. One of the big things to remember is these people are losing a lot of protein and a lot of food, going down the drain, and they must be fed. We mustn't starve them the way we used to do. Another treatment I have heard good things from of late is treatment with the amino acids. What is more, here is an idea that I think few of us, perhaps, ever had before. In order to digest, we must have ferments in the intestine; we must have juices, and those juices contain protein. If the patient is not getting much protein and the rest is going down the drain, he can't make ferments. That is why sometimes, after giving the amino acids, the results have been spectacular. The patient has gone on digesting again.

COARCTATION OF AORTA

QUESTION: Dr. Kerr, what is the oldest age at which operation for coarctation of the aorta would be feasible?

DR. WILLIAM J. KERR, San Francisco: There have been few of these operations to date. I know of only seven or eight. I think, probably, one would get the best results if it was done during the early years or during youth. But it should be kept in mind that the longer the patient lives the better the collateral circulation. One need have little fear of clamping off the aorta under those circumstances, because there is already an adequate supply without anything going through this channel, or very little. I think there is less chance of damage to the spinal cord under these circumstances. But I think it is hard to answer that question categorically; one would think around the age of 50 or 60 or 70, especially if the patient had arterial changes, one might hesitate to do that.

MEDICAL TREATMENT OF GOITER

QUESTION: Dr. Rynearson, does it appear that recent advances in the medical treatment of goiter may supplant surgery?

DR. EDWARD H. RYNEARSON, Rochester, Minn.: These first two reports were turned over to you and me only on May 11, 1946. All of us have known that these studies were in progress, but this is the first time the medical profession as a whole has had the opportunity of reviewing the experiences of the Boston group. As far as I know, the group in San Francisco and the Bay District have not yet reported their results in the literature. It is by all odds the most important and fascinating thing which has come out in the treatment of goiter. I am just a little afraid, however, that we may forget the previous work, the use of the goiter genes which Astor and Williams and the others started. Of these two methods, there will undoubtedly be something forthcoming which will greatly help our handling of the hyperthyroid patient. Certainly the goiter genes already have helped you and me get patients ready for surgery, whom we have had a most difficult time getting ready before. So that as of July 5, 1946 I should say that the goiter genes have proved to have their principal role in the proper preoperative preparation of patients, and that this new principle, the radioactive iodine, suggests from the paper Chapman gave and from the articles which you and I have had a chance to read, here may be a lead toward eliminating the surgeons.

DR. KERR: It should be kept in mind in connection with this type of treatment with radioactive isotypes of iodine that it is still a destructive process. As Dr. Rynearson suggests, if we go back through history in the treatment of goiter we shall find that practically all the methods that have any value, outside of the use of iodine and some of the other drugs, are all destructive: injection of boiling water, putting in bare radon tubes or the use of x-ray treatment or surgical removal. They are all destructive methods, and so is this. The advantage here is that the radioactive material apparently goes to the most hyperplastic and most actively proliferating cells. I believe that, under proper control, this method may entirely replace the other destructive methods, including surgical treatment for hyperplastic goiter.

SCHISTOSOMIASIS

QUESTION: Dr. Faust, would you briefly comment on the modern clinical treatment of schistosomiasis?

DR. ERNEST C. FAUST, New Orleans: As I indicated previously, there is not as yet available for clinical use any new preparation. However, we have gone back to the oldest one used, used since 1918, namely antimony and potassium tartrate. By slightly changing the method of administration, in other words injecting 0.5 per cent solution rather than 2 to 6 per cent solution, the tolerance has been greatly increased. Within a period of slightly less than one month, giving it once a day intravenously on alternate days, we are able to introduce approximately 0.5 Gm. of metallic antimony. While there are some relapses, the results have been very satisfactory in comparison with the other antimonials which have been administered. There are these things which must be kept in mind, namely that a few people are intolerant and have uncontrollable bronchial spasm; some have uncontrollable nausea and vomiting, and one thing which I think we should definitely keep in mind because we now know a little about it, namely that a large amount of antimony is deposited in the thyroid gland, so that in the cases of hyperthyroidism it may be that antimony is contraindicated.

PENICILLIN IN PNEUMONIAS

QUESTION: Dr. Reimann, some one wishes to know whether all pneumonias should be treated with penicillin.

DR. HOBART A. REIMANN, Philadelphia: As I think you can gather from what I said before, my opinion on that point is that all patients with pneumonia should be treated with penicillin, but the recommendation should be qualified. When, for example, the practitioner in the country has to deal with a patient suddenly taken with a severe form of pneumonia, I think he is perfectly justified in giving the patient sulfonamides but preferably penicillin. The same qualifications obtain here that I mentioned before: If one treats the patient empirically, the penicillin or the sulfonamides should be given in large, recommended doses promptly and should be stopped within a reasonable time because of the danger of sulfonamide poisoning, which we have seen so often. I think the best answer to the question is that one has to use a good deal of judgment as to whether one is going to use either penicillin or sulfonamides for the pneumonias but probably make an etiologic diagnosis, if possible, beforehand.

VIRUS DISEASES

QUESTION: Dr. Schultz, what laboratory diagnostic procedures are of value to the practicing physician in virus diseases especially neurotropic or respiratory, and when should they be used?

DR. E. W. SCHULTZ, Stanford University, Calif.: In the neurotropic virus diseases we have little that can be of value in the immediate diagnosis. Most of it is in retrospect. The most helpful procedure is the collection of serum early in the disease and a repetition of this later on, and then tests for the presence of neutralizing antibodies, whether or not neutralizing antibodies have appeared. In certain of the encephalitides it is possible at times to isolate the virus from the blood. This is unlikely in this group of infections. Certainly there are no opportunities for demonstrating the virus in either blood or spinal fluid in poliomyelitis. In poliomyelitis the presence of virus in the stools may be demonstrated by inoculation of the fecal suspensions intranasally. In some instances the virus may be demonstrated in the nasopharyngeal secretions. In respiratory infections such as influenza it is possible to demonstrate the virus directly by inoculating it into mice or ferrets intranasally. I think that just about covers it, the most important test being the test for neutralizing antibodies in the blood.

RHEUMATIC DISEASE

Question: Dr. Hench, if a rheumatoid arthritic patient is sensitive to gold, what treatment do you use?

Dr. Philip S. Hench, Rochester, Minn.: One has to revert, of course, to the more conservative measures, which, I might add, in the hands of some men seem to be just as good as gold therapy. Of course, they are the removal of obvious areas of infection, the institution of a program of rest so the inflamed joints would not be traumatized by occupation and recreation unduly, and, perhaps, the use of physical therapy daily in their own home, supplemented by professional physical therapy, which will relieve pain and relieve muscle spasm, and then, perhaps, vaccine therapy.

HYPERTENSION

Question: Dr. Kerr, what is the most valuable method you employ in treating a hypertensive patient who appears to be steadily getting worse, that is, hypertension constantly increasing in an otherwise apparently normal adult?

Dr. Kerr: I assume that this is a patient who does not have an underlying nephritis. There is the problem, of course, of treating the patient from the psychologic standpoint, of giving the patient adequate rest during this time, although there are some who feel that the patient with hypertension has to be kept moving. There is a period when they are improved. I think the use of phenobarbital or some other sedative is of value at this time. If the heart is failing, obviously the heart requires its own treatment. During the last ten or fifteen years I have had a good deal of experience with patients who seemed to be doing badly, who had increased venous pressure, who had encephalopathy developing as well as cardiac failure, and some renal failure. I have found, in a high percentage of patients in this group, that the spinal fluid pressure was very high, up to 300, 400, 500, even up to 700 mm. of spinal fluid. They may have ocular manifestations during this time, even rapidly failing vision. By repeated spinal fluid removal of as much spinal fluid as can be taken out, the symptoms of headache, of visual disturbance, cardiac failure, even renal failure, may be eliminated or eradicated.

SEX HORMONES IN HEART DISEASE

Question: Dr. Kerr, have sex hormones any place in treating heart disease?

Dr. Kerr: I have not had any great experience with sex hormones in the treatment of heart disease. Many of us for a good many years have had the idea that if we gave too much of those substances to patients who had heart disease or hypertension it might even be dangerous. I don't know whether that is true, but it has been, of course, suggested. I haven't had enough experience so that I could pass any judgment on that. It does give some people a sense of well being to get something which they think might be helpful.

MALARIA

Question: Dr. Faust, what is the best method of treating the chronic recurrent malarial attacks in our returning Pacific veterans?

Dr. Faust: Ninety-nine per cent of the cases coming in from the Pacific—at least 99 per cent—are going to be the vivax type. The so-called benign but the very troublesome vivax type and the falciparum type have been, in all these cases, eliminated by adequate atabrine suppressive treatment in the field. If these cases have been proved to be resistant time and again to clinical administrations of atabrine, then quinine should be used at least until chloroquin becomes available, and the quinine would be given by oral administration, using 30 grains (2 Gm.) a day for a period of approximately six days, and then proceeding with 10 grains (0.65 Gm.) a day for a period of five to six weeks at most. When chloroquin becomes available 4½ grains (0.3 Gm.) given twice a day for the first day and then 4½ grains for the following three days will constitute a course of treatment. This is a better drug than atabrine, does not produce discoloration and has a much better record in reducing or completely eliminating relapse. So I think we can depend on it, in the course of the next several months, to give us an answer which will be much better than quinine or atabrine. But if the patient is now atabrine resistant, quinine is the present drug of choice.

THIOURACIL IN THYROTOXICOSIS

Question: Dr. Rynearson, in selected cases, that is those of poor surgical risk, or those who have recurrent thyrotoxicosis, would you condemn persistent thiouracil administration?

Dr. Rynearson: As of 1940, if we can use that, the deaths which were occurring in goiter surgery were pretty largely either those who had such severe cardiac failure secondary to adenomatous goiter, with hyperthyroidism or prolonged and unrecognized toxic diffuse goiter, they could not satisfactorily be prepared for operation. The second group was a large, unfortunately large, number of patients who had been put on 10 drops of iodine three times a day, week after week and month after month, and in some instances a year or longer. Those patients were terribly difficult to get ready for operation. With the use of thiouracil or thiobarbital or any one of the goiter genes we have at our disposal a better method than the use of iodine, even though it takes longer for preparing those patients for operation. The last report which I have had from Boston, where they have had the greatest experience in serving these patients, is that about 50 per cent of the patients in whom an attempt has been made to treat the hyperthyroidism medically, without operation, they have had recurrences of the hyperthyroidism, requiring thyroidectomy. Perhaps one third of the patients with hyperthyroidism can be controlled with these goiter genes, but in all instances it does offer an excellent method for preoperative medical treatment. It probably is not the answer to cases of severe goiter, from the standpoint of medical treatment without surgery.

SALICYLATES IN RHEUMATIC FEVER

Question: Dr. Reimann, some of the members would like to know a little more about your belief in the use of massive doses of salicylates for rheumatic fever and the method of administration.

Dr. Reimann: I have always been opposed to massive doses of drugs for any disease simply to bring the patient to the point of toxicity. I think there it is an error in judgment. Why give normal doses when smaller doses will produce the same clinical effect? With regard to salicylate therapy in acute rheumatic fever, we know the drug is not a specific in the sense of the term that it affects the disease mechanism, but it is a specific symptomatic agent. So, instead of giving the enormous doses of 10 Gm. intravenously which were once recommended, why not be satisfied with doses of 8 to 10 Gm. per day, which seems to control the symptoms as satisfactorily as larger doses, without having the danger of toxicity and even of death, which has occurred in a number of patients receiving this enormous dosage.

HISTAMINE IN GASTRIC ULCER

Question: Dr. Alvarez, several of the members would like to know something of the status of histamine in the treatment of ulcer. Is it felt that the degree of acidity is concerned in the actual development of the ulcer? What is the relationship between histamine and the treatment as outlined by Dr. Bernstein?

Dr. Alvarez: I can't see how on earth anybody would want to treat ulcer with histamine, which should raise the acidity. Actually, years ago, we had some experience with that, and it didn't work any too well. We were getting, first, mucin which was supposed to cure ulcer, as some of you may remember, and that mucin turned out to be just full of histamine, and it did not cure the patients. So that I would never think of giving histamine to my patients, and I would be an awful doubting Thomas. It would be very difficult, I think, to convince me that it was any good, because we do feel, I think practically all of us today, that the height of the acid has much to do with keeping an ulcer going.

POTASSIUM THIOCYANATE IN HYPERTENSION

QUESTION: Dr. Kerr, what is your attitude regarding the use of potassium thiocyanate in the treatment of hypertension?

DR. KERR: I have used it very little, and I don't think it is a drug that should be used generally unless one has adequate control of the blood levels. I don't think it is very often needed and, certainly it is not the real answer to hypertension. I seldom, if ever, use it.

CANCER OF UTERUS; METASTASES IN BONE

QUESTION: Dr. Adair, what about the therapy of carcinoma of the body of the uterus? Is there any relief experienced with large doses of testosterone propionate given three weeks for metastasis in bone, other than metastases in the breast?

DR. ADAIR: What is the treatment of cancer of the body of the uterus? That is surgical operation. Cancer of the cervix has had an interesting discussion during this convention, in that they are now separating about 10 per cent of the early carcinomas of the cervix and using radical surgery there, and that is new. I have had no experience with testosterone therapy in bone conditions other than metastases from cancer of the breast. I think it would be very illuminating to make further studies in that field. I have repeated recently the work of Hadow in England, who divided his elderly women with cancer of the breast, women from 60 on up, giving them large doses of the estrogens. I found that, to my great astonishment, I got 40 per cent improvement in patients who had metastatic lesions in the soft tissue. I have not yet had the opportunity to repeat that work in bone, which was a very striking piece of work, and it should be furthered and repeated by other workers.

PLASMOQUIN IN RELAPSING MALARIA

QUESTION: Does Dr. Faust feel that plasmoquin has no place in the treatment of relapsing Pacific malaria?

DR. FAUST: I think plasmoquin does have a place. Plasmoquin has this advantage, which atabrine, quinine and probably chloroquin and paliquin do not have: it sterilizes the gametocytes in the blood circulation so that the mosquitoes will be taking up sterile gametocytes when they take the blood. There is some indirect evidence also that plasmoquin gets down underneath the circulating malaria parasites, perhaps down into the sporozoitic foci, and sterilizes them there, perhaps actually cutting off, to a certain extent, their production. So that plasmoquin probably should always be recommended in conjunction with the main therapeutic, such as atabrine or quinine or chloroquin for this particular purpose or these two allied purposes.

POLIOMYELITIS

QUESTION: Dr. Schultz, should cases of poliomyelitis be isolated, and what technic of isolation should be used?

DR. SCHULTZ: We do not yet know how the disease is transmitted. All we know is that the virus is eliminated in the stools in rather large amounts, in some cases in the nasopharyngeal secretion. The connection between these two sources and the ultimate port of entry, which is also unknown, is not understood. I should think that isolation, complete isolation, is indicated, certainly until we know how the disease is transmitted, with particular attention to these two sources, and particularly the fecal source of the virus.

OBESITY

QUESTION: Dr. Rynearson, would you please list a few things which could be done for the obese patient that would promote safe weight reduction?

DR. RYNEARSON: Here again you run into a different concept of obesity, of two perfectly honest physicians approaching the same patient but with divergent opinions. I think the exhibit put on from the Department of Physiology of Northwestern University on the use of amphetamine as a treatment of obesity was fine. There, again, my interpretation, as I watched that exhibit, was this: that the use of that or other allied drugs has only one function, and that is to decrease the patient's appetite, in that case, human or canine; that the decrease in weight, again, as directly correlated with the number of calories ingested and the amount of calories utilized. I am therefore committed in my own thinking—I have had no reason to change it—that, if obesity is an endocrine problem, there still is no endocrine therapy for it. Nobody has ever used any endocrine extract which has caused them to lose an ounce, with the exception, of course, of adequate doses of thyroid. But even if it is an endocrine problem I know of no endocrine treatment. There has never been a patient in the history of the world who would fail to lose satisfactorily if that patient followed a diet sufficiently low in calories to permit weight reduction. If those two premises are correct, the safest and best treatment for obesity is a weight reduction program, making certain the patient has adequate mineral and vitamin supplements in which that diet is deficient. Beyond that I do not go. I have no particular feeling about the use of amphetamine except this: If the patient honestly wants to reduce, then that patient honestly will cooperate in limiting the calories. There never has been a failure, I wish to repeat, when an obese patient has failed to lose weight in following a rigid reduction regimen.

MINERAL OIL IN CONSTIPATION

QUESTION: Dr. Alvarez, is mineral oil a safe drug to be taken for constipation?

DR. ALVAREZ: I never heard of its killing anybody, so I guess it is safe that way. How anybody digests it at all, taking mineral oil, I don't know. We tell our patients, and most of them are perfectly willing to accept this dictum, that they musn't take cold, greasy food, and yet they take the food and pour cold, greasy oil on it and, what is more, an oil that is almost indigestible. Somehow or other they continue to digest. Some develop flatulence and indigestion, and some of them, of course, get into trouble after a while because the oil comes through unannounced. Then there is one other difficulty with the prolonged taking of oil: the feces are so soft that they do not dilate the anal ring and, as a result, these people get an anal ring which is very tight and sometimes has to be dilated or operated on. So I say to patients, if they want to take liquid petrolatum occasionally, it is all right; but to settle down to it for the rest of one's days I don't think is any good.

DR. KERR: I don't see how they get along without mineral oil in Minnesota. If you ever traveled through there on the train, you would realize during the wintertime, at least, that almost everybody must have constipation because it is so far out to the little house on the hill.

PENICILLIN IN ENDOCARDITIS

QUESTION: Dr. Reimann, what about the use of penicillin in subacute bacterial endocarditis?

DR. REIMANN: The use of penicillin for this serious disease has been one of the most striking advances in the field of treatment of infectious diseases. Heretofore we had no agent that was at all satisfactory, with perhaps, the exception of sulfonamide compounds, which weren't very satisfactory. Now we see report after report coming in of 50 to 60 per cent of patients cured with penicillin, followed two to three years. It will take longer before we can evaluate this, because even though the patient is cured from his original attack there is every possibility and chance that he will become at some future time reinfected, because the nidus of the disease or distorted valve is still present. There is nothing to prevent the reimplantation of a Streptococcus viridans on that valve in case it becomes bacteremia. That brings up the initial, important question, which there isn't time to discuss, about the management of patients who have had subacute bacterial endocarditis, should they have a cold or should they have operation. I think it would be most valuable to use penicillin in a prophylactic manner, again, only for a short time, either before or during the operation and stop it again.

THE BALTIMORE Rh TYPING LABORATORY

A New Community Public Health Service

MILTON S. SACKS, M.D.

and
WILLIAM J. KUHNS, M.S.
Baltimore

Subsequent to the initial report in 1940[1] of the discovery of the Rh factor in human red blood cells there has been a rapid succession of papers emphasizing the importance of this new knowledge to clinical medicine. The principal applications have been to certain problems of obstetrics and pediatrics and to transfusion therapy. Rh testing and studies of Rh isoimmunization, however, did not become widespread immediately for a variety of reasons. Among these may be mentioned the relative scarcity and expense of potent and reliable testing serums; the increasing antigenic complexity of the Rh factor, and technical problems associated with the demonstration of anti-Rh immune bodies. Sporadic studies were made in some obstetric patients whose previous histories were strongly suggestive of the effects of Rh incompatibility and in other persons in whom, in the course of receiving multiple transfusions, inexplicable reactions developed. As it became increasingly obvious that varying manifestations of congenital hemolytic disease were by no means uncommon and that there was serious potential danger to both the mother and her newborn child in absence of preexisting knowledge of the Rh status in pregnancy,[2] a number of obstetricians in Baltimore deemed it essential to establish facilities for routine Rh studies at a minimal cost for any clinic or private patient in the city.

OUTCOME OF PREGNANCY

Fig 1.—Front (top) and back (bottom) of history card

In the spring of 1945 the Obstetrical and Gynecological Section of the Baltimore City Medical Society appointed a committee to study the feasibility of establishing a central laboratory for Rh testing. Official public health agencies were unable, because of wartime problems, to assume the additional burdens which this work entailed, but the cooperation of the City Health Department was of great assistance in the operation of the laboratory. It was decided to establish the laboratory as a cooperative private venture under the sponsorship of the society. Funds sufficient for the purchase of equipment and the employment of trained personnel were contributed as loans by individual members of the section. Space was generously provided without charge by the University of Maryland School of Medicine. The laboratory began to function on Aug. 1, 1945.

Date

Dear Doctor:

PATIENT	TYPE	Rh.
	Anti Rh Titre	

All Rh neg. pregnant patients should be sent to the Laboratory for further testing in a month.

Send Husband of Rh. neg woman to Laboratory for Rh Typing.

There is no charge for these additional services.

Fig 2.—Physician's report card.

PLAN OF OPERATION

The laboratory is under the jurisdiction of a committee of six members of the local Obstetrical and Gynecological Society. One of us (M. S. S.) was appointed director. Two technicians, a research assistant, a stenographer, a maid and several part-time volunteers make up the rest of the staff. Services are offered free to dispensary patients of hospitals within the city and to patients of the City Health Department Obstetrical Clinics. Private patients pay $3 or $5, depending on whether their physician requests a serologic test for syphilis and a hemoglobin determination in addition to routine Rh typing and blood grouping. The initial charge is the only one; all subsequent studies throughout pregnancy are made without further cost to the patient. Similar arrangements have been made available to physicians in the counties of Maryland.

Miss L. Anne Hellen and Mrs. Lewis M. Hess assisted in the operation of the laboratory.

From the Baltimore Rh Typing Laboratory and the Department of Clinical Pathology, University of Maryland School of Medicine.

In the case of dispensary and clinic patients, blood samples are drawn in the various hospital outpatient departments and, through the cooperation of the City Health Department, are transported to a central point adjacent to this laboratory. Special cardboard boxes containing a test tube and a history card are distributed to the various hospitals and city obstetric clinics with the aid of the health department. Private patients receive appointment cards (fig. 3) from a stock furnished by the laboratory to all physicians requesting them. For the benefit of private patients certain hours on two specified days each week have been designated for the drawing of samples of blood. Each period is of three hours' duration. The arrangement is designed to take care of all patients referred by their physicians during the course of one week. Patients are occasionally seen at other times by special appointment. Laboratory periods are so spaced that all the tests on a given group of patients can be completed before the subsequent session.

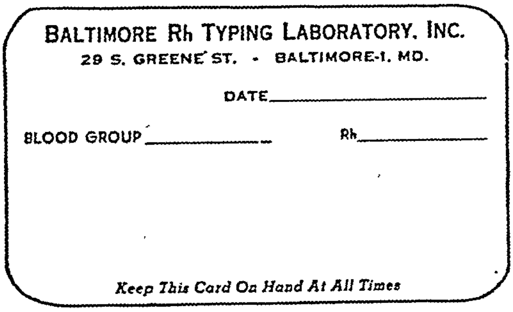
Fig. 3.—Patient appointment card.

All pertinent data concerning the patient are entered on a special history form (fig. 1). Blood groupings are performed as soon as possible after the conclusion of a blood-drawing session. Rh typing is then done with a potent human antiserum of Rh_0' (Rh_1) specificity. All samples of blood giving obviously positive reactions are thus screened out. Those blood samples giving negative or doubtful reactions are further tested with three other antiserums, including those of Rh′ and Rh″ specificity. The serums of all patients with Rh-negative blood are then tested for antibody content. For this purpose three tests are routinely performed: the blocking test, the conglutination test and the Diamond slide test.[3] If a positive reaction is obtained with any of these, titration of the antibody is attempted with the use of the conglutination technic of Wiener, as well as the standard procedure with a 2 per cent suspension of Rh positive cells in isotonic solution of sodium chloride. In this manner the presence in the serum of univalent (glutinins) or bivalent (agglutinins) antibodies, or both, is determined. Details are recorded on the history form. A special file is kept of all sensitized patients. Reports are sent promptly to the referring clinic or physician (fig. 2). The patient is sent a small card (fig. 4) on which her blood group and Rh type is indicated. The purpose of this is to obviate the necessity of a repetition of blood typing when the patient is admitted to a hospital for delivery.



BALTIMORE Rh TYPING LABORATORY, INC.

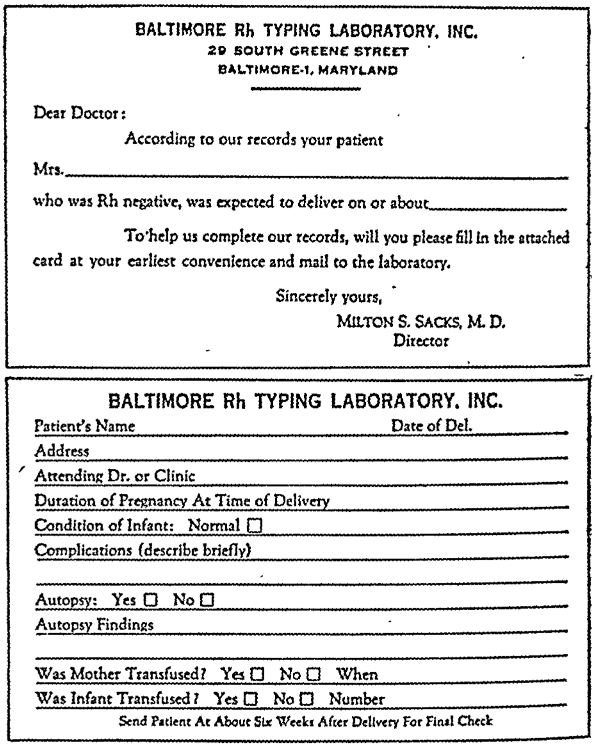
DATE________________

BLOOD GROUP__________ Rh__________

Keep This Card On Hand At All Times

Fig. 4.—Patient's blood group record.

The husbands of all women with Rh-negative blood are requested to come to the laboratory for typing. Women whose husbands are found to have Rh-negative blood are not required to return to the laboratory for further testing. If the husband is found to be Rh-positive and of subgroup Rh_0' (Rh_1) or Rh′, his blood cells are Hr typed to determine whether he is homozygous or heterozygous.[4] This information is, of course, particularly important in the case of sensitized women with Rh-negative blood who have previously given birth to erythroblastotic infants.



BALTIMORE Rh TYPING LABORATORY, INC.

Autopsy: Yes ☐ No ☐
Autopsy Findings
Was Mother Transfused? Yes ☐ No ☐ When
Was Infant Transfused? Yes ☐ No ☐ Number
Send Patient At About Six Weeks After Delivery For Final Check

Fig. 5.—Front (top) and back (bottom) of follow-up card.

All women with Rh-negative blood whose husbands have Rh positive blood are followed at monthly intervals throughout the first and second trimesters of pregnancy and at closer intervals in the third trimester. The earliest evidences of sensitization are thus immediately detected and reported to the attending physician.

Patient's records are transferred from the active (pregnant) Rh-negative file to the inactive file at the termination of pregnancy. Special follow-up cards (fig. 5) are sent to the referring physician or clinic requesting information in regard to the outcome of the pregnancy. When these are returned they are clipped to the patient's history and become part of the permanent record. Samples of the patient's blood are studied at ten days and six weeks post partum as a final check for the presence of antibodies.

COMMENT

The accumulation of mass data is essential to the proper evaluation and solution of the many problems still associated with heterospecific pregnancies. In most instances Rh heterospecificity is responsible for the varied manifestations of congenital hemolytic disease, but recent studies indicate the occasional involvement of maternal-fetal differences in regard to the A-B-O and M-N agglutinogens. For reasons cited earlier in this paper widespread adoption of Rh testing procedures has been retarded in spite of demonstrated value. At the present stage of development Rh studies, particularly those associated with the demonstration of the presence and character of antibodies, lend themselves well to centralization. The enthusiasm and success with which the establishment of this privately sponsored cooperative laboratory has been received attest to this fact. During the first eight months of its existence, the laboratory performed tests on approximately 7,000 pregnant women. There were approximately 12,000 births in Baltimore during a similar period. Even on the low fee basis, $3 to $5 for private patients, the laboratory has more than maintained itself, establishing a sizable sinking fund for the future.

To date, the proportions of Rh-positive and Rh-negative persons conform closely to previously established figures. The opportunity to study distribution of the Rh subgroups has so far been limited by the scarcity of necessary serums. Such studies are now in progress. Of a group of 904 Rh-negative pregnant women, 46, or 5.08 per cent, displayed evidences of sensitization. Detailed studies of this group also are now in progress. It is obvious that knowledge of the existence of sensitization in a particular patient will be of value in the prevention of intragroup hemolytic transfusion reactions. Future sensitization of women with Rh-negative blood by the unwitting transfusion of Rh-positive blood should also be prevented to a large extent.

Current methods for the prevention and management of congenital hemolytic disease are admittedly not too satisfactory. The detection and availability of a fairly large group of sensitized patients will permit the application and study of new technics for the better handling of this important clinical entity.

Among the byproducts of the operation of the laboratory are (1) maintenance of a continuous supply of potent serum by voluntary venesection of Rh-sensitized women whose serums contain bivalent antibodies, (2) accumulation of a large list, available to all hospitals in the city, of Rh-negative men of all blood groups who are willing to serve as volunteer or professional donors in an emergency and (3) application of Rh tests in medicolegal problems which involve disputed paternity.

SUMMARY

1. The Baltimore Rh Typing Laboratory, a privately sponsored cooperative community venture, began to function Aug. 1, 1945.

2. The services of the laboratory are available to private and clinic patients at a moderate fee. All pertinent data are kept in a permanent file and Rh study as a routine part of prenatal care has been performed on 7,000 women in the first eight months of the laboratory establishment.

3. The accumulation of mass data on Rh-sensitized patients will permit the application and study of new technics for preventing congenital hemolytic disease.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
CHICAGO

(Continued from page 923)

(Note.—*Following is the seventh chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of The Journal. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in The Journal. *The complete work will be published in book form It is hoped to have it available by the time of the annual session.*—Ed.)

CHAPTER 7. *The End of the First Decade*

Viewing the development of the American Medical Association during the first few years of its existence, Dr. Nathan Smith Davis called attention to the factor which gave force to the activities of the organization. It seemed evident to him that many members had failed to perceive clearly the true relations of the American Medical Association to the medical profession. "They seem to look upon the national organization," he said, "in the same light as a representative civil government, whose acts were laws of binding import and whose basis of representation must consequently be adjusted with the same nice care to the equality of diverse or separate interests." It seemed to be forgotten that the Association was entirely a voluntary organization the acts of which carried with them no other force than the inherent justice of the acts themselves, coupled with the *moral* weight of the body from which they emanated; and that this *moral* weight would bear a close relation to the fulness of representation from those institutions whose interests were most involved in the movements proposed.

1853

NEW YORK CITY

Several years after the preliminary meeting was held in New York in 1846, the American Medical Association met in the Bleecker Street Presbyterian Church. The chairman of the Committee of Arrangements and Reception, Dr. F. Campbell Stewart, expressed the pride of New Yorkers at the triumphant success that had followed the movement originating in their state. At this meeting thirty states and territories, the District of Columbia, the Army and Navy of the United States and the American Medical Society in Paris were represented. The attendance was 573.

A resolution from the Medical Society of Virginia urged the American Medical Association to consider the propriety of appointing some distinguished and well qualified chemist (not a practitioner of medicine) to analyze the prominent nostrums of the day as far as practical and to publish the result of such an analysis monthly in the most extensively circulated newspaper in each state in the Union represented in the Association.

LICENSURE AND EDUCATION

Again the Association indicated its interest in medical education and in epidemiology. Special committees were appointed to urge the passing of legislation for licensure of physicians in the individual states. Indeed one resolution was introduced urging that a student be not admitted to any medical school until he had graduated at some literary institution and was found to possess an English and classical education. Interesting too was a movement to compel the graduates of medical schools to take an oath to conform strictly to the code of ethics of their alma mater and to give to the faculty a right to withdraw the diploma in case the oath should be violated.

A resolution was introduced for the investigation of the value of galvanism as a therapeutic agent.

ACCOMPLISHMENTS OF THE ASSOCIATION

In the presidential address, Dr. Beverley R. Wellford of Virginia summarized in one paragraph the accomplishments of the American Medical Association in its first seven years. He was answering charges made in some quarters that the Association had as yet effected nothing. Some had affirmed that the Association had injured the profession in public estimation by exposing its deficiencies and had thus induced the patronage of homeopathy and other delusions of similar character. To this Dr. Wellford replied:

> But, gentlemen, if it be nothing to have reduced an amorphous, chaotic, professional mass to something like symmetry and order; nothing, to have awakened attention to important defects in preliminary and medical education, and, in some measure, to have removed them; nothing, to have caused the establishment and reorganization of local and State medical societies; nothing, to have caused the enactment of wholesome laws, both by the Federal and State Governments; nothing, to have produced scientific papers of acknowledged ability and erudition; nothing, to have awakened dormant talent, and elicited a vernal bloom, which promises a rich harvest of autumnal fruit; nothing, to have acquired a reputation, which renders even its membership a title of honour and distinction; is it also nothing, by unaided, intrinsic moral power, to have bound in one code of medical ethics, thousands of men in every section of this wide Union, each one free to act according to his own individual views, but yielding them in cheerful obedience to the opinions of the Association, with as much deference and submission as if it were armed with the power and the terrors of penal law? Is it nothing, unendowed with the compulsory authority of legal enactment, or the seductive influence of mileage and per diem pay, annually to convoke such an assembly, as I have now the honour to address? Gentlemen, such a congress, of such materials, and under such circumstances, presents a spectacle of moral beauty, to which the opponents of medical reform cannot be insensible. It must command their respect and admiration, even if it fail to secure their co-operation. I know not, gentlemen, what may be the effect on others of an occasion like this, but for my single self, when I thus recognize the denizen of the city and the forest; him of the frozen north and of the sunny south; him of the mountains, the rivers, and the prairies of the west, with him from the borders of the broad Atlantic bringing their various opinions and prejudices, and casting them together, as a sacrificial offering on the altar of science and professional patriotism; when I see them animated by the same honourable and lofty impulse, and, in fraternal harmony, uniting their efforts to attain the same grand results, I feel an honest pride in my profession and my country, and an abiding confidence, that, to such sons, the high destinies of both may be safely intrusted.

By this time Dr. N. S. Davis had begun to manifest his special interest in the medical literature of the day; he had now become chairman of the Committee on Medical Literature. He presented a report calling attention to the transactions of the individual state medical societies and the various monographs and books that had been published during the year. Much of his report dealt with his concept of the true functions of the editors of medical journals.

The prize essay was an article on "The Cell: Its Physiology, Pathology, and Philosophy; as Deduced from Original [illegible] Which Is Added Its History and Cr[illegible] J. Burnett of Boston.

1854

ST. LOUIS

The President, Dr. Jonathan Knight, was unable to attend the St. Louis session in 1854; hence the address for the occasion was presented by the Vice President, Dr. Usher Parsons of Rhode Island.

The prize essay was that of Dr. Daniel Brainard of Chicago. The title was "Essay on a New Method of Treating Ununited Fractures and Certain Deformities of the Osseous System." Each of the contestants identified his essay with an appropriate quotation. Daniel Brainard chose a quotation from Ambroise Paré, which is one of the great classics of medical science:

> notwithstanding all the pains that I have heretofore taken, I have reason to praise God, in that it hath pleased Him to call me to that branch of Medical practice, commonly called Surgery, which can neither be bought by gold, nor by silver, but by industry alone, and long experience.

Already some attention began to be given to pedagogics in medicine; a resolution was offered, though promptly rejected, "that the practice of professors' reading lectures to their classes, no matter with how much care selected from the musty records of antiquity, is a miserable apology for teaching, is *primâ facie* evidence of their inaptitude to instruct, and is inimical to medical progress."

DRIED MILK

Well in advance of the times also was a resolution offered by Dr. N. S. Davis calling the attention of the Association to the "great sacrifice of health and life which takes place annually, especially among children in large cities, on account of the difficulty of procuring a proper supply of pure and wholesome milk; and the great importance of devising some mode by which the nutritious constituents of the milk can be preserved in their purity and sweetness for such purposes." He exhibited to the Association a specimen of dried milk which had been placed in his hands and which was represented to be capable of preserving all the qualities of the milk perfectly for any length of time. This, it must be remembered, was in the year 1854.

At this time an announcement greeted with great pleasure was made by the local Committee on Arrangements. All the railroads, except the New York and Hudson River Railroad, had granted to the members of the American Medical Association free passage to their homes.

ALCOHOLIC LIQUORS

Another resolution urged that a committee be appointed to examine into and report on the effects of alcoholic liquors taken into the system on health and disease.

A final action failed to be taken on a resolution that the cultivation and practice of specialties in medicine and surgery are legitimate and honorable pursuits and meet the approval of the Association and that the same avenues for announcing his calling to the public that are recognized as proper to the general practitioner are open to the specialist.

On Friday morning, May 6, 1853, the day after the adjournment of the sixth annual meeting of the American Medical Association held in the city of New York, a train of the New York and New Haven Railroad passing through Norwalk, Conn., fell into the Norwalk River through an open drawbridge. Forty-four passengers of the ill fated train were suddenly deprived of life, among them seven physicians returning from the convention. As a memorial to these physicians the convention in 1854 published a record of their medical careers.

1855

PHILADELPHIA

By 1855 the number of prize essays, which had numbered a score or more at previous meetings, had steadily diminished. Only six essays were available for consideration by the Committee on Prize Essays in 1855. Only one of these was considered worthy of notice—a paper on "Statistics of Placenta Previa" by James D. Trask of White Plains, Westchester County, N. Y.

Well in advance of the times, however, was a resolution urging the secretary of the Association to offer every facility possible to the reporters of the public press to enable them to furnish full and accurate reports of the transactions.

As an indication that the nature of man does not change, it became necessary, previous to reading a report on the "Hygrometrical States of the Atmosphere in Various Localities, and Its Influence on Health," which was seriously interrupted by the loud conversation of members, to pass a resolution, unanimously, "that all the desultory conversation of members be done down stairs."

Realizing the importance of vital statistics, a resolution was introduced urging the Association to petition legislative bodies in the individual states to collect their vital statistics.

HOMEOPATHY VS. REGULAR MEDICINE

For the first time the battle between homeopathy and regular medicine reared its ugly head in the convention. Because the legislature of Michigan, in contravention to the charter of the University of Michigan, had put in a chair of homeopathy, a resolution was offered "That any such unnatural union as the mingling of an exclusive system, such as homeopathy, with scientific medicine in a school, setting aside all questions of its untruthfulness, cannot fail, by the destruction of union and confidence, and the production of confusion and disorder, unsettling and distracting the mind of the learners, to so far impair the usefulness of teaching as to render every school adopting such a policy unworthy of the support of the profession." This resolution was passed unanimously by the Association.

THE STATE SOCIETIES

For the first time also the authority of the national body in relation to state societies came into question; it was resolved that no state or local society should be entitled to representation in this Association which had not adopted its code of ethics, that no state or local society which has violated or discarded any article or clause should be entitled to representation and that since the State Medical Society of Ohio had violated one of the articles of the code of ethics by adopting a resolution "That it is not derogatory to medical dignity, or inconsistent with medical honor, for medical gentlemen to take out a patent right for surgical or medical instruments," therefore, be it resolved "that the secretary of this Association be directed to inform the officers of the State Medical Society of Ohio that, unless such action be rescinded, it cannot hereafter be represented in this Association."

1856

DETROIT

The "Firemen's Hall" in Detroit was the place of assemblage for the 1856 session. The number of delegates had fallen to 208, representing nineteen states, the Minnesota Territory and the United States Army.

Perhaps most significant of the considerations were those related to medical literature, urging a wider use of American articles and American medical textbooks in teaching.

The number of essays submitted for prizes had fallen still further; a resolution suggested that hereafter the money be awarded for the best essay founded on original investigations of the author.

A committee was established to classify those diseases which involved a derangement of the mental manifestations.

An expression of thanks was tendered to the Fire Department of the City of Detroit for the use of its large and commodious hall. Also it was resolved "that the urbane deportment and the elegant hospitalities of the profession and private individuals, as well as the polite attentions of citizens generally, demand of this Association a high appreciation of the cultivated manners of this city of the West, and which has tended greatly to enhance the pleasure of the session here of the delegates from abroad."

The President of the Association gloried in the progress that it had made in uniting the medical profession so that it could speak with one voice and in rallying physicians everywhere around higher standards.

AMERICAN MEDICAL LITERATURE

S. D. Gross of Louisville presented the significant report on American medical literature, analyzing the causes for its backwardness in the tradition of the original essay by Oliver Wendell Holmes. His main criticism was a lack of independence in the journalism of that day with its leaning on materials coming from abroad. He urged physicians to utilize their private and hospital practice for the study of cases which should be reported in American medical journals. And he offered as a resolution "That this Association earnestly and respectfully recommend, first, the universal adoption, whenever practicable, by our schools, of American works as textbooks for their pupils; secondly, the discontinuance of the practice of editing foreign writings; thirdly, a more independent course of the medical periodical press toward foreign productions, and a more liberal one toward American; and, fourthly, a better and more efficient employment of the facts which are continually furnished by our public institutions for the elucidation of the nature of diseases and accidents and, indirectly, for the formation of an original, a vigorous and an independent national medical literature.

"That we venerate the writings of the great medical men, past and present, of our country, and that we consider them as an important element of our professional and national glory.

"That we shall always hail with pleasure any useful or valuable works emanating from the English press, and that we shall always extend to them a cordial welcome as books of reference, to acquaint us with the progress of legitimate medicine abroad, and to enlighten us in regard to any new facts of which they may be the repositories."

Significant also was the report of the Committee on Plans for Organization of State and County Societies. It worked toward a unified organization, and it prepared the first constitution and by-laws for a state medical society.

1857

NASHVILLE

Nashville, Tenn., welcomed the doctors for the tenth annual meeting in 1857; bursts of Southern oratory reverberated in the air. Following is a paragraph from the address of welcome by Dr. C. K. Winston:

> You are the representatives of a profession distinguished alike for its antiquity, its scientific attainments and its usefulness. It constitutes the true link between science and philanthropy—science and philanthropy, moral, intellectual and physical. You come from every portion of this glorious republic—from the Kennebec to the Rio Grande—from orange groves and golden sands—from mountains clad in eternal snow and valleys smiling in perpetual verdure. You come not for purposes of self aggrandizement or personal ambition, nor yet to advance the schemes of parties or stir up the antipathies of sections. "You know no North, no South, no East, no West"; but you come as a company of philanthropists, a band of brethren, that you may pour the acquisitions of another year into a common treasury, kneel side by side at a common altar and drink the living water as it gushes from a common fountain. You have come to maintain the dignity, to elevate the ensign of a profession to which you have devoted your lives and to which you have linked your fortunes.

Protests were made against the admission of delegates from the Oglethorpe Medical College, Savannah, on the ground that the professorships had not been filled in physiology and materia medica at its sessions, but investigation revealed that all of the chairs but one had been filled and that the man was sick, so that the college was permitted to have its delegates.

Some of the committees which had regularly reported began to report that they had no report.

Now there began apparently to be some despair at the failure to progress in regulating education. Following a resolution demanding a minimum number of teachers and hours of study, an alternative resolution was offered to the effect that the Association did not have the power to control medical education and that it had most signally failed in its objective and had already introduced elements of discord. It was therefore recommended that a special committee be appointed to advise a system of medical instruction under which all medical institutions should be organized. There was great discussion but to no purpose.

A constitution for the state societies was adopted and, after hearing a number of scientific reports, the convention adjourned.

EDITORIAL OPINION OF THE ASSOCIATION

In 1855 Dr. D. M. Reese, editor of the *American Medical Gazette,* satirically minimized the work of the American Medical Association up to that time, saying:

> The conviction appears to be general, among writers, that notwithstanding the numerous reforms attempted, recommended and resolved on by repeated *"whereases"* and reiterated at every successive meeting by high-sounding resolutions, and published in each volume of the *Transactions,* yet, in *effectuating any one of these, after seven years' trial, the efforts of the Association in this regard have resulted in signal and utter failure.*

Editors of some other medical journals gave rise to sentiments of similar import. Dr. Nathan Smith Davis told them that their announcements of policy were premature. "It must be borne in mind," he said, "that our country is made up of more than thirty separate states; that the Association was, and is, not only destitute of legislative powers itself but also without access to any one legislative body possessing authority to regulate the education and interests of the profession of the whole country."

Little could any one have thought that another half century at least would be required before sufficient public opinion could be mustered within and without the medical profession to undertake a real drive for high standards in medical education.

Dr. B. Dowler, then editor of the *New Orleans Medical and Surgical Journal,* summarized the accomplishments of the first ten years of the American Medical Association in these words:

> As a social and professional *reunion* of kindred spirits and great minds, its memories afford perennial delight. It has given impetus to the progress of medical polity and science; it exercises moral suasion rather than that of authority; it has brought together a bright constellation of intellect, cemented the bonds of friendship among good men and true, and should it fail to effectuate its original and grand finality—that is, a thorough reform in medical education—it will leave a luminous track of light in the moral firmament of the Aesculapian heavens, throughout the expansions of the Republic.

Clinical Notes, Suggestions and New Instruments

TWO DEATHS ASSOCIATED WITH SUPRADIAPHRAGMATIC VAGOTOMY

CARNES WEEKS, M.D.
BERNARD J. RYAN, M.D.
and
JOE M. VAN HOY, M.D.
New York

Supradiaphragmatic vagotomy has been associated with complications which resulted in death in 2 cases.

CASE 1.—*History.*—S. H., a white man aged 47, an unemployed salesman, was admitted to the First Surgical Division of Bellevue Hospital complaining of severe burning epigastric pain. He had had a known duodenal ulcer since 1931, with massive hematemeses on three occasions. Roentgenograms at another hospital one month before admission to Bellevue had again confirmed the diagnosis of duodenal ulcer. There was no evidence of obstruction, but pain had persisted since 1931 despite diet and an ulcer management regimen which had been punctuated by alcoholic bouts on frequent occasions.

Two years prior to admission he noted the onset of headache, nocturia and frequency. He was examined by a physician and told that he had hypertension. Since that time his bloood pressure had ranged continuously in the vicinity of 220 systolic and 140 diastolic. He had had frequent headaches and had been unable to concentrate for the past two years.

Physical Examination.—The patient was a middle-aged white man of florid complexion who was uneasy and restless. Relevant observations were limited to the following: The apex impulse of the heart was felt at the midclavicular line. The rhythm was regular and the beat was forceful. There were no murmurs. The blood pressure was 210 systolic and 140 diastolic. There was moderate tenderness in the epigastrium

---

From the First Surgical (Columbia) Division, Bellevue Hospital.

and both upper quadrants of the abdomen without spasm or rebound tenderness.

Laboratory Examination.—The hemoglobin level of the blood was 13.5 Gm. per hundred cubic centimeters; the white blood cells numbered 6,200; the Wassermann test was negative. Urinanalysis was negative with a specific gravity of 1.015; the nonprotein nitrogen level was 45 mg. per hundred cubic centimeters. Gastric analysis showed that the free hydrochloric acid was 110 units and the total acidity was 130 units one hour after histamine stimulation. A roentgenologic examination of the chest revealed moderate enlargement of the heart in the transverse diameter.

Course.—Because of the duration and severity of the patient's symptoms, it was decided that surgical intervention was indicated for his duodenal ulcer. It was planned to do a supradiaphragmatic vagotomy and if feasible at the time of the operation to perform a left thoracolumbar sympathectomy for his hypertension. He was prepared for the surgical procedure for four weeks on the hospital ward with frequent feedings and the intravenous administration of Amigen. He gained seven pounds (3 Kg.) during this time.

On June 19, 1946 a thoracotomy was performed with removal of the ninth rib on the left side. Both vagal trunks were well developed as they lay beside the lower third of the esophagus. Sections 3 cm. in length of both the right and the left vagus nerves were removed just above the diaphragm. The left thoracolumbar sympathetic chain was then removed from the fifth dorsal to the second lumbar nerve, inclusive, as well as the greater, lesser and least splanchnic nerves in this area. Microscopic examination showed that the tissue removed was typical of sympathetic ganglions and nerves. Subsequent to this surgical procedure, the patient did well, had a good appetite and did not complain of epigastric pain or distress. Gastric dilatation which developed on the fifth and sixth postoperative days was relieved by gastric aspiration.

On July 2, 1946 a right thoracolumbar sympathectomy, similar in extent to that on the left, was performed. The patient did well immediately after the operation but had gastric dilatation which was relieved by aspiration on the third, fourth, fifth and sixth postoperative days. His condition then gradually began to deteriorate. He became difficult to manage on the ward, could not get on with other patients and refused to keep himself clean or to cooperate with other patients. He demanded paraldehyde at frequent intervals and required large doses of chloralhydrate, barbiturate or paraldehyde to furnish adequate sedation. Except for anorexia, his complaints were not referable to his abdomen or his gastrointestinal tract to any degree but consisted chiefly of restlessness, anxiety and irritability. A psychiatric consultant made the diagnosis of anxiety neurosis. During this time he was up and about the ward but had extremely disturbed nights.

On the morning of July 17, 1946, fifteen days after the second stage of his thoracolumbar sympathectomy, the intern on the ward was called because the patient was being especially noisy. At that time he complained of pain in the lower quadrant on the right and left side. Examination of the abdomen was unsatisfactory because of the restlessness and uncooperativeness of the patient; the only positive observation was slight diffuse abdominal tenderness. Two hours later he suddenly went into shock, becoming cold, clammy and comatose, and passed a tarry stool. Blood pressure and radial pulse was unobtainable. He received oxygen, stimulants, 1,500 cc. of whole blood and 500 cc. of plasma but failed to respond and died twelve hours later.

Report of Autopsy.—Relevant observations at autopsy were limited to the following: An examination of the cranial cavity and brain was performed. The heart weighed 640 Gm. and the left side was hypertrophied. On opening the abdominal cavity, a good deal of foul-smelling gas escaped. There was about 1,500 cc. of brownish cloudy fluid and gross food particles in the abdominal cavity. The peritoneal surfaces were rough and not of their usual shiny appearance. The first part of the duodenum showed an indurated ulcerated area, rather sharply demarcated, with a perforation about 2.5 cm. in diameter through which gross particles had passed into the abdominal cavity. Section of tissue of the duodenal lesion revealed the typical microscopic picture of duodenal ulcer.

Comment.—This is the first reported case of a perforation of a duodenal ulcer following vagotomy. However, it is probably also the only case in which vagotomy has been combined with bilateral thoracolumbar sympathectomy. The sympathectomy may well have been the cause of failure here, since simultaneous ablation of the sympathetic nerves could have neutralized the beneficial effects of the vagotomy. The patient's failure to have the acute pain ordinarily associated with a perforated peptic ulcer may have been due to the removal of viscerosensory fibers probably associated with the sympathetic side of the autonomic nervous system.

CASE 2.—*History.*—B. M., a white man aged 55, who had been totally blind for fourteen years, was admitted to the First Surgical Division of Bellevue Hospital on July 11, 1946 complaining of epigastric pain of four days' duration. He had had a duodenal ulcer diagnosed roentgenologically at another hospital nine years previously. He had been treated during the interim on a medical regimen with diet and Sippy treatment. Recurrence of his symptoms required an admission to the medical service of Bellvue Hospital in 1940.

Physical Examination.—The patient was a middle-aged white man who was totally blind. Relevant observations were limited to the following: There were multiple excoriations of the skin of both legs and of the trunk, extending up as high as the neck. There were several lesions suggestive of scabetic burrows. The pupils did not react to light, there was no light perception, and the fundi showed optic atrophy bilaterally. The right arm had been disarticulated at the shoulder, and there was an old amputation of the tip of the right great toe. There was moderate tenderness with slight spasm in the right epigastrium. The heart was regular in rhythm and lacked enlargement, thrills or murmurs. The blood pressure was 140 systolic and 90 diastolic.

Laboratory Examination.—The red blood cell count was 4,110,000; the hemoglobin level was 11.0 Gm. per hundred cubic centimeters. Urinalysis was negative; the stool guaiac test was 3 plus on one occasion; the Wassermann test was negative. The overnight total gastric secretion was 0.430 cc., the fasting acidity was 63 units, the total acidity 89 units. The serum amylase determination was 53.4 units. Roentgenologic examination of the stomach and duodenum showed an ulcer of the first portion of the duodenum without disturbance of gastric motor function.

Course.—The patient was placed on rest in bed and on a progressive Sippy diet with a colloidal suspension of aluminum hydroxide given at the bedside. The scabies was satisfactorily treated with 5 per cent precipitated sulfur in wool fat and white ointment. The eye consultant believed that the optic atrophy of the patient was secondary to poisoning with methyl alcohol. The pain in his epigastrium continued intermittently. Due to the long standing history, the lack of satisfactory response to medicaments and the patient's inability to care for himself properly, it was decided that a surgical operation on the ulcers should be performed.

On Aug. 6, 1946 a thoracotomy was performed with removal of the eighth rib on the left side from the transverse process to the cartilaginous junction. The lung was densely adherent over its costal and diaphragmatic surfaces and was freed by sharp dissection. A small rent which was made in the lower part of the left lobe at the fissure was sutured with interrupted mattress sutures of fine catgut on an atraumatic needle. After freeing and delivering the lower esophagus just above the diaphragm, the right vagus nerve was identified and freed from its attachment to the esophagus for 5 cm. above the diaphragm. A bradycardia resulted, and the upper portion of the nerve was injected with a 1 per cent solution of procaine hydrochloride. About 4 cm. of the nerve was removed.

A few moments after sectioning the nerve, it was noted that the pulse had slowed to a rate of between 60 and 70. Shortly thereafter the anesthetist stated that she was having some difficulty with the patient's respiration. A wet pad was placed over the wound and all manipulations were halted. The anesthetist then noted that the patient's pulse had suddenly become and that we shall always extend to them a cordial welcome as books of reference, to acquaint us with the progress of legitimate medicine abroad, and to enlighten us in regard to any new facts of which they may be the repositories."

Significant also was the report of the Committee on Plans for Organization of State and County Societies. It worked toward a unified organization, and it prepared the first constitution and by-laws for a state medical society.

1857

NASHVILLE

Nashville, Tenn., welcomed the doctors for the tenth annual meeting in 1857; bursts of Southern oratory reverberated in the air. Following is a paragraph from the address of welcome by Dr. C. K. Winston:

> You are the representatives of a profession distinguished alike for its antiquity, its scientific attainments and its usefulness. It constitutes the true link between science and philanthropy—science and philanthropy, moral, intellectual and physical. You come from every portion of this glorious republic—from the Kennebec to the Rio Grande—from orange groves and golden sands—from mountains clad in eternal snow and valleys smiling in perpetual verdure. You come not for purposes of self aggrandizement or personal ambition, nor yet to advance the schemes of parties or stir up the antipathies of sections. "You know no North, no South, no East, no West"; but you come as a company of philanthropists, a band of brethren, that you may pour the acquisitions of another year into a common treasury, kneel side by side at a common altar and drink the living water as it gushes from a common fountain. You have come to maintain the dignity, to elevate the ensign of a profession to which you have devoted your lives and to which you have linked your fortunes.

Protests were made against the admission of delegates from the Oglethorpe Medical College, Savannah, on the ground that the professorships had not been filled in physiology and materia medica at its sessions, but investigation revealed that all of the chairs but one had been filled and that the man was sick, so that the college was permitted to have its delegates.

Some of the committees which had regularly reported began to report that they had no report.

Now there began apparently to be some despair at the failure to progress in regulating education. Following a resolution demanding a minimum number of teachers and hours of study, an alternative resolution was offered to the effect that the Association did not have the power to control medical education and that it had most signally failed in its objective and had already introduced elements of discord. It was therefore recommended that a special committee be appointed to advise a system of medical instruction under which all medical institutions should be organized. There was great discussion but to no purpose.

A constitution for the state societies was adopted and, after hearing a number of scientific reports, the convention adjourned.

EDITORIAL OPINION OF THE ASSOCIATION

In 1855 Dr. D. M. Reese, editor of the *American Medical Gazette,* satirically minimized the work of the American Medical Association up to that time, saying:

> The conviction appears to be general, among writers, that notwithstanding the numerous reforms attempted, recommended and resolved on by repeated "*whereases*" and reiterated at every successive meeting by high-sounding resolutions, and published in each volume of the *Transactions,* yet, in *effectuating any one of these, after seven years' trial, the efforts of the Association in this regard have resulted in signal and utter failure.*

Editors of some other medical journals gave rise to sentiments of similar import. Dr. Nathan Smith Davis told them that their announcements of policy were premature. "It must be borne in mind," he said, "that our country is made up of more than thirty separate states; that the Association was, and is, not only destitute of legislative powers itself but also without access to any one legislative body possessing authority to regulate the education and interests of the profession of the whole country."

Little could any one have thought that another half century at least would be required before sufficient public opinion could be mustered within and without the medical profession to undertake a real drive for high standards in medical education.

Dr. B. Dowler, then editor of the *New Orleans Medical and Surgical Journal,* summarized the accomplishments of the first ten years of the American Medical Association in these words:

> As a social and professional *reunion* of kindred spirits and *great minds, its memories afford perennial delight. It has given impetus to the progress of medical polity* and science; it exercises moral suasion rather than that of authority; it has brought together a bright constellation of intellect, cemented the bonds of friendship among good men and true, and should it fail to effectuate its original and grand finality—that is, a thorough reform in medical education—it will leave a luminous track of light in the moral firmament of the Aesculapian heavens throughout the expansions of the Republic.

Clinical Notes, Suggestions and New Instruments

TWO DEATHS ASSOCIATED WITH SUPRADIAPHRAGMATIC VAGOTOMY

CARNES WEEKS, M.D.
BERNARD J. RYAN, M.D.
and
JOE M. VAN HOY, M.D.
New York

Supradiaphragmatic vagotomy has been associated with complications which resulted in death in 2 cases.

CASE 1.—*History.*—S. H., a white man aged 47, an unemployed salesman, was admitted to the First Surgical Division of Bellevue Hospital complaining of severe burning epigastric pain. He had had a known duodenal ulcer since 1931, with massive hematemeses on three occasions. Roentgenograms at *another hospital one month before admission to* Bellevue had again confirmed the diagnosis of duodenal ulcer. There was no evidence of obstruction, but pain had persisted since 1931 despite diet and an ulcer management regimen which had been punctuated by alcoholic bouts on frequent occasions.

Two years prior to admission he noted the onset of headache nocturia and frequency. He was examined by a physician and told that he had hypertension.' Since that time his blood pressure had ranged continuously in the vicinity of 220 systolic and 140 diastolic. He had had frequent headaches and had been unable to concentrate for the past two years.

Physical Examination.—The patient was a middle-aged white man of florid complexion who was uneasy and restless. Relevant observations were limited to the following: *The* apex impulse of the heart was felt at the midclavicular line. The rhythm was regular and the beat was forceful. There were no murmurs. The blood pressure was 210 systolic and 14 diastolic. There was moderate tenderness in the epigastrium

and both upper quadrants of the abdomen without spasm or rebound tenderness.

Laboratory Examination.—The hemoglobin level of the blood was 13.5 Gm. per hundred cubic centimeters; the white blood cells numbered 6,200; the Wassermann test was negative. Urinanalysis was negative with a specific gravity of 1.015; the nonprotein nitrogen level was 45 mg. per hundred cubic centimeters. Gastric analysis showed that the free hydrochloric acid was 110 units and the total acidity was 130 units one hour after histamine stimulation. A roentgenologic examination of the chest revealed moderate enlargement of the heart in the transverse diameter.

Course.—Because of the duration and severity of the patient's symptoms, it was decided that surgical intervention was indicated for his duodenal ulcer. It was planned to do a supradiaphragmatic vagotomy and if feasible at the time of the operation to perform a left thoracolumbar sympathectomy for his hypertension. He was prepared for the surgical procedure for four weeks on the hospital ward with frequent feedings and the intravenous administration of Amigen. He gained seven pounds (3 Kg.) during this time.

On June 19, 1946 a thoracotomy was performed with removal of the ninth rib on the left side. Both vagal trunks were well developed as they lay beside the lower third of the esophagus. Sections 3 cm. in length of both the right and the left vagus nerves were removed just above the diaphragm. The left thoracolumbar sympathetic chain was then removed from the fifth dorsal to the second lumbar nerve, inclusive, as well as the greater, lesser and least splanchnic nerves in this area. Microscopic examination showed that the tissue removed was typical of sympathetic ganglions and nerves. Subsequent to this surgical procedure, the patient did well, had a good appetite and did not complain of epigastric pain or distress. Gastric dilatation which developed on the fifth and sixth postoperative days was relieved by gastric aspiration.

On July 2, 1946 a right thoracolumbar sympathectomy, similar in extent to that on the left, was performed. The patient did well immediately after the operation but had gastric dilatation which was relieved by aspiration on the third, fourth, fifth and sixth postoperative days. His condition then gradually began to deteriorate. He became difficult to manage on the ward, could not get on with other patients and refused to keep himself clean or to cooperate with other patients. He demanded paraldehyde at frequent intervals and required large doses of chloralhydrate, barbiturate or paraldehyde to furnish adequate sedation. Except for anorexia, his complaints were not referable to his abdomen or his gastrointestinal tract to any degree but consisted chiefly of restlessness, anxiety and irritability. A psychiatric consultant made the diagnosis of anxiety neurosis. During this time he was up and about the ward but had extremely disturbed nights.

On the morning of July 17, 1946, fifteen days after the second stage of his thoracolumbar sympathectomy, the intern on the ward was called because the patient was being especially noisy. At that time he complained of pain in the lower quadrant on the right and left side. Examination of the abdomen was unsatisfactory because of the restlessness and uncooperativeness of the patient; the only positive observation was slight diffuse abdominal tenderness. Two hours later he suddenly went into shock, becoming cold, clammy and comatose, and passed a tarry stool. Blood pressure and radial pulse was unobtainable. He received oxygen, stimulants, 1,500 cc. of whole blood and 500 cc. of plasma but failed to respond and died twelve hours later.

Report of Autopsy.—Relevant observations at autopsy were limited to the following: An examination of the cranial cavity and brain was performed. The heart weighed 640 Gm. and the left side was hypertrophied. On opening the abdominal cavity, a good deal of foul-smelling gas escaped. There was about 1,500 cc. of brownish cloudy fluid and gross food particles in the abdominal cavity. The peritoneal surfaces were rough and not of their usual shiny appearance. The first part of the duodenum showed an indurated ulcerated area, rather sharply demarcated, with a perforation about 2.5 cm. in diameter through which gross particles had passed into the abdominal cavity. Section of tissue of the duodenal lesion revealed the typical microscopic picture of duodenal ulcer.

Comment.—This is the first reported case of a perforation of a duodenal ulcer following vagotomy. However, it is probably also the only case in which vagotomy has been combined with bilateral thoracolumbar sympathectomy. The sympathectomy may well have been the cause of failure here, since simultaneous ablation of the sympathetic nerves could have neutralized the beneficial effects of the vagotomy. The patient's failure to have the acute pain ordinarily associated with a perforated peptic ulcer may have been due to the removal of viscerosensory fibers probably associated with the sympathetic side of the autonomic nervous system.

CASE 2.—*History.*—B. M., a white man aged 55, who had been totally blind for fourteen years, was admitted to the First Surgical Division of Bellevue Hospital on July 11, 1946 complaining of epigastric pain of four days' duration. He had had a duodenal ulcer diagnosed roentgenologically at another hospital nine years previously. He had been treated during the interim on a medical regimen with diet and Sippy treatment. Recurrence of his symptoms required an admission to the medical service of Bellvue Hospital in 1940.

Physical Examination.—The patient was a middle-aged white man who was totally blind. Relevant observations were limited to the following: There were multiple excoriations of the skin of both legs and of the trunk, extending up as high as the neck. There were several lesions suggestive of scabetic burrows. The pupils did not react to light, there was no light perception, and the fundi showed optic atrophy bilaterally. The right arm had been disarticulated at the shoulder, and there was an old amputation of the tip of the right great toe. There was moderate tenderness with slight spasm in the right epigastrium. The heart was regular in rhythm and lacked enlargement, thrills or murmurs. The blood pressure was 140 systolic and 90 diastolic.

Laboratory Examination.—The red blood cell count was 4,110,000; the hemoglobin level was 11.0 Gm. per hundred cubic centimeters. Urinalysis was negative; the stool guaiac test was 3 plus on one occasion; the Wassermann test was negative. The overnight total gastric secretion was 0.430 cc., the fasting acidity was 63 units, the total acidity 89 units. The serum amylase determination was 53.4 units. Roentgenologic examination of the stomach and duodenum showed an ulcer of the first portion of the duodenum without disturbance of gastric motor function.

Course.—The patient was placed on rest in bed and on a progressive Sippy diet with a colloidal suspension of aluminum hydroxide given at the bedside. The scabies was satisfactorily treated with 5 per cent precipitated sulfur in wool fat and white ointment. The eye consultant believed that the optic atrophy of the patient was secondary to poisoning with methyl alcohol. The pain in his epigastrium continued intermittently. Due to the long standing history, the lack of satisfactory response to medicaments and the patient's inability to care for himself properly, it was decided that a surgical operation on the ulcers should be performed.

On Aug. 6, 1946 a thoracotomy was performed with removal of the eighth rib on the left side from the transverse process to the cartilaginous junction. The lung was densely adherent over its costal and diaphragmatic surfaces and was freed by sharp dissection. A small rent which was made in the lower part of the left lobe at the fissure was sutured with interrupted mattress sutures of fine catgut on an atraumatic needle. After freeing and delivering the lower esophagus just above the diaphragm, the right vagus nerve was identified and freed from its attachment to the esophagus for 5 cm. above the diaphragm. A bradycardia resulted, and the upper portion of the nerve was injected with a 1 per cent solution of procaine hydrochloride. About 4 cm. of the nerve was removed.

A few moments after sectioning the nerve, it was noted that the pulse had slowed to a rate of between 60 and 70. Shortly thereafter the anesthetist stated that she was having some difficulty with the patient's respiration. A wet pad was placed over the wound and all manipulations were halted. The anesthetist then noted that the patient's pulse had suddenly become imperceptible, and on examination the heart beat was found to be absent. An opening was made in the pericardium, and massage of the heart was performed rhythmically. Oxygen was administered under pressure and 0.6 mg. of atropine was administered intravenously. After several minutes the heart began to beat feebly and irregularly. After continued massage for a few more minutes, the heart action became stronger and resumed a normal rhythm for a short while. It was necessary to massage the heart intermittently to maintain this rhythm.

When the heart was observed to be beating regularly and more forcefully, rib spreaders were removed and preparation was made to close the thoracic cage. The action of the heart, however, again became feeble and irregular and massage was reinstituted. Intravenous procaine hydrochloride (50 mg.) and repeated doses of atropine were administered to the patient for another hour. Intercardiac epinephrine was finally used as well without success. Normal cardiac action could not again be reestablished despite one hour and twenty minutes of cardiac massage, and the patient was pronounced dead at that time. Permission for an autopsy was not obtained. Microscopic examination of the specimen of vagus nerve removed showed typical nerve fibers.

Comment.—Since permission for autopsy was not obtained, assessment as to the cause of death must be in part speculative. The difficulty developed directly after manipulation and division of the right vagus nerve. Since respirations persisted after the circulatory collapse it may well be inferred that death was primarily associated with disturbance in the cardiovascular mechanism.

A somewhat similar case is reported by Moore, Chapman, Schulz and Jones.[1] The patient expired approximately forty-eight hours postoperatively of difficulties either related to the anesthesia or that could have resulted from hyperirritability of the autonomic nervous system with the setting up of vagovagal reflexes and resultant cardiac standstill. Since this experience the authors [1] have routinely anesthetized both vagus nerves above the point of manipulation with procaine hydrochloride and have given rather large doses of atropine either before or during the operation.

Reid and Brace [2] showed electrocardiographic changes consisting of extra systoles, both auricular and ventricular, delayed conduction time, slowing of the heart and ventricular escape during tracheal and bronchial manipulations with the various mechanical appliances used in closed types of anesthesia. Soma Weiss and Ferris produced similar electrocardiographic tracings by inflating a balloon in an esophageal diverticulum.[3] This leads one to suggest that manipulation of the vagus itself may often have a profound and occasionally an extremely deleterious effect on the cardiac mechanism.

A Peripheral Nerve Registry.—Perhaps the most significant contribution made by army neurosurgeons during the war had to do with peripheral nerve injuries. This is a problem which can be solved only during war. The busiest civilian clinics do not see enough material to permit authoritative conclusions as to the management of these injuries. Unfortunately, in World War I, in spite of the large number of peripheral nerve injuries, the opportunity was lost, because no comprehensive and accurate follow-up studies were made. We are now in process of finding out exactly what happens to peripheral nerve injuries and how they are best treated. A peripheral nerve registry was instituted in the early months of 1944 and to date some 8,000 peripheral nerve sutures have been registered in it and are being reported on, as to progress, at regular intervals. Plans have been made to transfer the registry to the Veterans Administration for the final phase of the study, with Colonel Woodhall, who initiated the undertaking, remaining in charge of it.—Spurling, R. Glen: Neurosurgery in World War II, *Bull. U. S. Army M. Dept.*, December 1946.

Council on Pharmacy and Chemistry

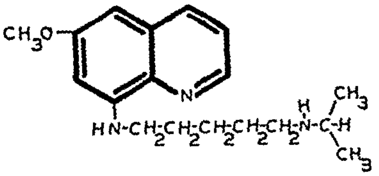
REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., *Secretary.*

PENTAQUINE, NONPROPRIETARY NAME FOR 6-METHOXY-8-(5-ISOPROPYLAMINOAMYLAMINO)-QUINOLINE

Recently there has been developed a new effective antimalarial chemical compound known as SN 13,276 having the following structural formula:



6-Methoxy-8-(5-isopropylaminoamylamino)-quinoline.

The compound was investigated through parallel studies with pamaquine and other 8-aminoquinolines, conducted at civilian centers under the sponsorship of the Committee on Medical Research of the Office of Scientific Research and Development and various army installations.

Through a spokesman for the Board for the Coordination of Antimalarial Studies, it was proposed that the Council give consideration to the name Pentaquine as a suitable designation for this compound.

After due consideration of its antimalarial status and deliberation to ascertain the chemical suitability and freedom from confusion with other names now in use in this country, the Council voted to adopt the proposed name Pentaquine as the nonproprietary name for the new antimalarial compound previously designated as Sn 13,276.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

PHENOBARBITAL (See New and Nonofficial Remedies, 1946, p. 530).

The following dosage forms have been accepted:

THE HARROWER LABORATORY, INC., GLENDALE, CALIF.

Tablets Phenobarbital: 32 mg.

THE VALE CHEMICAL CO., INC., ALLENTOWN, PA.

Tablets Phenobarbital: 16 mg., 32 mg. and 0.1 Gm.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1946, p. 618).

The following dosage forms have been accepted:

WILLIAM H. RORER, INC., PHILADELPHIA

Tablets Thiamine Hydrochloride: 1 mg. and 5 mg.

Solution Thiamine Hydrochloride, 50 mg. per cc.: 10 cc. vials. Preserved with 0.5 per cent chlorobutanol.

BACTERIAL VACCINE MADE FROM HEMOPHILUS PERTUSSIS (See THE JOURNAL, Jan. 5, 1946, p. 31).

The following dosage forms have been accepted:

E. R. SQUIBB & SONS, NEW YORK

Pertussis Vaccine (Single Strength): 8 cc. and 24 cc. vials. 10,000 million *H. pertussis* per cubic centimeter. Preserved with phenol 0.5 per cent.

Pertussis Vaccine (Double Strength): 5 cc. and 20 cc. vials. 20,000 million *H. pertussis* per cubic centimeter. Preserved with phenol 0.5 per cent.

PERTUSSIS VACCINE ALUM PRECIPITATED (See THE JOURNAL, Jan. 5, 1946, p. 31).
The following dosage form has been accepted:

THE UPJOHN CO., KALAMAZOO, MICH.

Pertussis Vaccine (Alum Precipitated): 3 cc. vials (one immunization) and 10 cc. vials (three immunizations). 10,000 million *H. pertussis* per cubic centimeter. Preserved with phenol 0.5 per cent.

PERTUSSIS VACCINE COMBINED WITH DIPHTHERIA TOXOID (See THE JOURNAL, Jan. 5, 1946).
The following dosage form has been accepted:

THE UPJOHN CO., KALAMAZOO, MICH.

Pertussis Vaccine, Diphtheria Toxoid, Combined, Alum Precipitated: 3 cc. vials (one immunization) and 10 cc. vials (three immunizations). 10,000 million *H. pertussis* per cubic centimeter. Preserved with sodium ethyl mercuri thiosalicylate 1 : 10,000.

PENICILLIN OINTMENT (See THE JOURNAL, Nov. 2, 1946, p. 515).
The following dosage form has been accepted:

SCHENLEY LABORATORIES, INC., LAWRENCEBURG, IND.

Penicillin Calcium Ophthalmic Ointment: 3.54 Gm. tubes. Each gram contains 2,000 units of penicillin calcium in white petrolatum, U. S. P.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1946, p. 286).
The following dosage form has been accepted:

THE HARROWER LABORATORY, INC., GLENDALE, CALIF.

Capsules Ephedrine Sulfate: 24 mg. and 49 mg.

Council on Physical Medicine

The Council on Physical Medicine has authorized the following report for publication on the recommendation of its Consultants on Contraceptive Devices. The Council wishes to express its appreciation for the valuable assistance rendered in the preparation of this report to its consultants: Drs. Nicholas J. Eastman, Walter W. Greulich, Joseph Hughes, Andrew C. Ivy (Chairman), Walter J. Meek and Ephraim Shorr.

HOWARD A. CARTER, *Secretary.*

REQUIREMENTS FOR ACCEPTABILITY OF CONTRACEPTIVE DEVICES

The following requirements for the acceptability of contraceptive devices of a physical nature, such as diaphragms and caps, stems and rings, tampons and sponges, devices for insertion, condoms and sheaths, have been proposed by the Consultants on Contraceptive Devices of the Council on Physical Medicine. These have been adopted by the Council, but it should be emphasized that they may be changed from time to time as the evidence indicates.

I. *Acceptable Evidence:*

A. Medical evidence to be acceptable must have been collected by physicians with special experience in the field of contraception or obstetrics and gynecology.

B. Evidence regarding the physical and chemical characteristics of the device must have been collected by individuals competent in the field.

II. *Efficacy:*

The device shall meet the following test of effectiveness: Each patient shall be observed for a minimum of twelve months. The minimum patient-years experience shall be seventy-five years. This may be obtained by observing 75 patients for one year, 50 patients for eighteen months or preferably 38 patients for two years or 25 patients for three years. Only patients pronounced as presumably fertile shall be used. If patients are excluded from the series on the basis of their being irregular users, the number excluded and the nature of the evidence justifying their exclusion shall be provided. The device shall provide a degree of protection as great as is consistent with good practice concerning the article under consideration, the protection to be obtained in women who have been compared with others habitually practicing no contraception.

III. *Harmlessness:*

A. Evidence shall be submitted showing that 100 or more couples have used the device on six or more occasions without subjective injury or sensations of pain, distress or discomfort. The refusal rate and the cause thereof shall be provided for this group of 100 patients and for the group of patients used for obtaining seventy-five or more patient-years of experience.

B. Evidence shall be required showing that the device had been used by 20 or more patients on twenty-one successive days without irritation or injury or evidence of physical damage as disclosed by examination with a speculum. This evidence is to be supplied in addition to similar evidence obtained on the group of patients used to establish efficacy in seventy-five patient-years of experience.

C. Where the device is a brand of a type previously known to or accepted by the Council on Physical Medicine, the evidence required by the two preceding paragraphs may be waived.

IV. *Design:*

A. The design of the device and accessories shall be satisfactory to the Council.

B. If a syringe applicator or nozzle is furnished for use in connection with a jelly or cream, it shall be sufficiently translucent to permit the detection of air which might lead to inadequate dosage.

V. *Durability:*

A. Condoms must have a shelf life of at least one year, and the date of expiration shall be stamped on the package so as to be readily seen by the purchaser. The shelf life test shall be conducted at a temperature of 37 C. and a humidity of from 10 to 30 per cent. At the end of the test or the expiration date stamped on the package, the condom shall not permit the passage of air when it is distended with air under a pressure of 0.2 pound per square inch and immersed in water.

B. The package containing a diaphragm shall be stamped with the date of manufacture. The instructions packed with the diaphragm shall show the date of manufacture, and the instructions shall provide the life expectancy on the basis of evidence submitted to the Council regarding the shelf life and the use life in combination, and when used with a known and acceptable jelly or cream. At the end of the life expectancy claimed, the diaphragm shall not permit the passage of water or a methylene blue solution under a pressure of ½ pound per square inch, the test being conducted so as to detect leaks about the rim.

VI. *Directions to Users and Advertising:*

A. The directions shall include a warning that the user should not expose the device to agents such as ordinary oils and greases or hot water, which will damage the device. Evidence shall be submitted showing the ordinarily available agents which damage and do not damage the device.

B. The directions shall include the appropriate means for cleansing the device.

C. The directions packed with each device whose performance depends on an intact membrane shall direct the user to inspect the device for holes and tears and to discard it if one is found.

D. The advertising and directions of the manufacturer shall make it clear that contraceptive diaphragms (and caps), tampons and sponges are intended for use in conjunction with spermicidal jelly or cream and should direct attention only to those accepted by the Council on Pharmacy and Chemistry.

E. The advertising and directions must not state or imply that the appropriate diaphragm or cap, or other device, can be chosen without the aid of a physician.

F. The advertising and directions and other printed matter packed with the device shall be satisfactory to the Council.

G. The results of the investigation by the Council of devices submitted will be published, but the use of the "seal of acceptance" will not be allowed.

SATURDAY, DECEMBER 21, 1946

THE HOUSE OF DELEGATES MID-WINTER SESSION

The first interim session of the House of Delegates was held in Chicago at the headquarters of the American Medical Association, December 9 to 11. The attendance by practically every delegate entitled to be present or by an alternate indicated the interest in the work of the organization.

Among the topics considered attention centered particularly on the report relative to the public relations of the Association; the revision of the Constitution and By-Laws; continued progress in the development of prepayment plans for medical costs; the medical care of miners, with a report by Admiral Boone on the survey now being conducted under his direction; the establishment of representation for the Veterans Administration in the Fellowship of the Association and in the House of Delegates; membership for general practitioners on hospital staffs; the plans for celebration of the centennial of the American Medical Association, and the report of the judicial council on brutal experiments by Nazi physicians. Other resolutions dealt with the functions of various agencies of the American Medical Association.

In this issue appear some of the minutes of the proceedings of the House of Delegates. The remainder will be published in issues that follow. Much of the discussion was held in executive session, and because it deals with intimate affairs of the Association these proceedings will appear in condensed form. As was emphasized in The Journal after the annual session of the Association last June, the report on public relations led to actions of the Board of Trustees making immediately effective certain recommendations. Thus there is now in the headquarters of the Association a division of public relations under an executive assistant to the general manager. This division will have the responsibility for the public relations activities of all councils, bureaus, publications and other agencies and operations of the Association. The activities include the preparation of a news letter for county and state medical societies; releases of information to the press and radio; assistance in the preparation of pamphlets and brochures, and the general function of interpretation of the Association and its work to the public.

A significant action of the House of Delegates was the amendment of the By-Laws so that general officers and delegates will now be eligible for election to the presidency of the Association. In former years it has been necessary for the person selected for such honor to resign from the position held before nomination could be made.

So significant were many of the actions taken by this session of the House of Delegates that it is hoped every physician will study the minutes carefully. The amazing rapidity of growth of the Association and the multiplicity of its functions have indicated for some time the necessity for more formal assignment of various activities and considerations to its various agencies. No doubt increased efficiency will become apparent as these measures begin to be properly established and coordinated.

FRIEDLÄNDER'S PNEUMONIA

Friedländer in 1882 described an encapsulated bacillus[1] which he believed was the chief etiologic agent of lobar pneumonia. His report was based, unfortunately, on postmortem findings, which, judged by more modern bacteriologic experience, are of doubtful value. A few years later other investigators[2] demonstrated conclusively that the common cause of lobar pneumonia is the pneumococcus. Nevertheless the concept that Friedländer's bacillus is associated with pneumonia and other respiratory tract infections pervaded textbooks and periodical medical literature for more than fifty years. Some investigators found that pneumonia due primarily to Friedländer's bacillus is relatively uncommon, if not a clinical rarity. Other writers have contended that in a small though definite percentage of cases of pneumonia Friedländer's-bacillus is the primary cause.

Baehr, Shwartzman and Greenspan[3] reported that only 2 proved cases of primary Friedländer's pneumonia were observed at the Mount Sinai Hospital in New York in thirty-six years. The 198 Friedländer bacillus infections reported by them were in large part of the gastrointestinal tract, the genitourinary tract and the biliary tract; pneumonia and other upper respiratory infections were fourth in their list. Of 61 cases in which the intra-abdominal suppuration was apparently due to this organism, 53 were abscesses of the appendix. Friedländer's bacillus was far more commonly found in infections following perforations of the intestinal tract than in infections of any other organ. They reported

[3] *Baehr, George; Shwartzman, Gregory,* and Greenspan, Edward B.: Bacillus Friedländer Infections, Ann. Int. Med. **10:** 1788 (June) 1937.

46 cases of suppurative infections of the biliary tract, in 43 of which Friedländer's bacillus was present in the pus in pure culture. The mortality among the 46 cases was high, owing in part to abscesses of the liver secondary to infection of the gallbladder or biliary passages. Recently[4] the first case of primary peritonitis caused by Friedländer's bacillus was reported. In this unusual case, in which rapid recovery occurred under sulfadiazine therapy, the pharynx was thought to be the port of entry of the bacillus to the blood stream through which the peritoneum was infected. Friedländer's bacillus, cultures of which were taken from the pharynx in this case four days after admission, is a normal inhabitant of the upper respiratory tract in a small percentage of normal persons.

Solomon[5] reviewed the pneumonia records of four medical divisions of the Bellevue Hospital from 1920 to about 1937 and found 32 acute cases of primary pneumonia caused by Friedländer's bacillus alone, not including 10 chronic cases and a large number in which Friedländer's bacillus was found in association with the pneumococcus, streptococcus or tubercle bacillus. Friedländer's pneumonia, Solomon believes, is much more common than is generally realized. The diagnosis can be readily suspected and quickly confirmed if its distinguishing features are kept in mind. The prognosis is more serious than in pneumonia due to other organisms.

Friedländer's bacillus (Bacillus mucosus capsulatus, the pneumobacillus or Klebsiella pneumoniae) is sometimes long, sometimes almost coccoid, nonmotile and gram negative. Julianelle[6] classified the strains by immunologic reactions into three specific types, A, B and C, which comprise the great majority of strains noted clinically. The distinctions in type depend on the presence of a specific carbohydrate in the capsular material, slightly different for each type, which is the soluble specific substance excreted in the urine. As with other organisms, both smooth and rough strains are found. Smooth strains produce capsules, are type specific and are highly virulent; the rough strains do not produce capsules and are not pathogenic.

Friedländer's pneumonia is said to comprise from 0.5 to more than 5 per cent of all cases of pneumonia. In the 5,000 cases of pneumonia reviewed by Solomon, among which 32 due to Friedländer's bacillus were found, the incidence was about 0.6 per cent, which was considered unquestionably low for reasons stated.

Certain characteristics distinguish the cases from the usual cases of pneumonia or other pulmonary conditions. Friedländer's pneumonia occurs in the later decades, the average age being 48.7 years. There is a distinct preponderance of males over females, the ratio being 7 to 1. Hemoptysis frequently occurs with the onset. Herpes is not common. The temperature is less regular. Low grade fever is much more common than in pneumococcic pneumonia. Involvement of the upper lobe and of more than one lobe is frequent. The sputum is a brick red, homogeneous emulsion of blood and mucus, in contrast to the ropy rusty sputum of pneumococcic pneumonia. Friedländer's bacillus is found in pure culture in the sputum and frequently in the blood culture. The mortality rate is high, and death occurs in an earlier stage of the disease than in pneumococcic pneumonia.

THERAPEUTIC POSSIBILITIES OF CURARE

Claude Bernard demonstrated that curare acts not on the nerve or on the muscle but on the myoneural junction. He pointed out the necessity of isolating the active chemical principle of the crude drug. This was accomplished by King and by Wintersteiner and Dutcher. The isolated pure crystalline substance, tubocurarine, belongs to a group of compounds known as *quaternary ammonium salts.* These salts possess the property of paralyzing neuromuscular conduction at the myoneural junction. The present day concept of curare therapy, according to Schlesinger,[1] does not propose to paralyze the myoneural junction but to create a block to the abnormal impulses imposed on the myoneural junction by the disease. A therapeutic effect is obtained without the loss of voluntary power.

Schlesinger reports the therapeutic effects in a group of 200 patients who have received a total of 1,500 injections of a suspension of d-tubocurarine chloride in white wax and oil. The proportions of the suspension are 3 per cent tubocurarine in 4.8 per cent wax in peanut oil. One cc. of the suspension contains the equivalent of 175 units of standard curare. The preparation is well standardized and its action predictable, milligram for milligram. It is given by either the subcutaneous or the intramuscular route. The following types of disorders were reported in this series: I. Muscle spasm, as in (*a*) direct trauma to muscle, (*b*) low back syndrome, (*c*) orthopedic deformities with reflex spasm, (*d*) myositis, (*e*) arthritis. II. Spasticity, as in (*a*) degenerative diseases of the central nervous system, (1) multiple sclerosis, (2) disseminated sclerosis, (3) familial lateral sclerosis; (*b*) spinal cord injury, (*c*) cerebrovascular disease, (*d*) tumors of the brain and spinal cord. III. Spasticity with dystonic features (Little's disease, cerebral diplegia). IV. Dystonia and athetosis. V. Rigidity, as in Parkinson's syndrome.

In the group characterized by spasm the results were gratifying, all degrees of spasm yielding to treatment, although when the pain was based on root compression, residual root pain remained after complete reduction of reflex muscle spasm. This response, according to Schlesinger, can be used diagnostically in ruling out root compression as a causative factor in a clinical picture. In the spastic group it was found generally possible to increase motor efficiency by eliminating the increased excitability of the stretch reflex. It was always possible to increase the patient's motor power by reducing the spastic element. Voluntary power was unaffected at dosage levels sufficient to relieve spasticity. In every case the gait was improved by this effect. Retraining enhanced this new level of performance strikingly. In the group of birth injuries, cerebral diplegia or spasticity with dystonic features, improvements were obtained in this sequence: (1) speech, (2) ability to sit quietly, (3) gait and (4) eating, writing and the performance of all skilled motor activities. These patients have maintained their improvement on doses twice weekly. In dystonia and athetosis it was possible to reduce spontaneous movements so that patients could sit quietly for reasonable periods, make active exercise and motor training possible and improve sleep. In patients with Parkinson's disease it was possible partially to relieve rigidity and to improve sleep. Toxic effects on any organ or system or changes in body economy or general well being were not noted. There was no tendency to habituation. There exist certain contraindications to the curare therapy, in particular any myasthenic tendency and kidney disease.

Current Comment

SYNTHESIS OF PENICILLIN

Eleven months ago the first announcement of the probable chemical nature of penicillin, a joint report of the American and British investigators in this field,[1] appeared in *Science*. At this time two possible formulas were presented which differed only in subtle molecular rearrangements. Recently du Vigneaud and his associates[2] have succeeded in synthesizing penicillin; they coupled penicillamine, a compound related to the unnatural isomer of the amino acid cysteine, with an oxazolone. It was proved conclusively, by using many of the newer tools of science, that penicillin was synthesized in these reactions. The actual reactions involved in this synthesis are still too complicated to warrant the definite statement that the synthesis proves the structure of the compound. While the amounts of penicillin synthesized were minute, the great importance of this accomplishment is that new drugs related to penicillin can now be produced. There is no indication that this accomplishment will permit the production of synthetic penicillin commercially in the near future or in any way affect the price of present commercial supplies.

ARMY DEFERMENT OF INTERNS

A recent directive from the War Department provides for an extension of deferments for 1,500 interns who hold army commissions. The directive is given elsewhere (page 1017) in this issue. For 1,200 interns the extension will be from July 1, 1947 to Jan. 1, 1948. For 300 there will be a deferment from July 1, 1947 to July 1, 1948. In regard to the latter group, "priority will be given to university and teaching hospitals." It is urged by the Council on Medical Education and Hospitals that hospitals utilize these men on an internship basis so that residency places available for veterans who are physicians will not be reduced in number. Intern officers and hospital authorities should become familiar with the new regulations at once, since deferments will be granted on a first come, first served, basis until the quota is filled.

EFFECT OF ANTIRETICULAR CYTOTOXIC SERUM ON THE HEALING OF FRACTURES

In 1944 Bogomolets[1] reported that experiments on 800 rabbits indicated that small doses of antireticular cytotoxic serum accelerated the healing time of fractures about one and one-half times as compared with the healing of fractures in nonstimulated animals. Large doses of the serum apparently retarded the healing time of the fractured bones. Control experiments utilizing the serum of a nonimmunized animal of the same species did not have the stimulating effect that antireticular cytotoxic serum had, thus demonstrating that the stimulating action of the antireticular cytotoxic serum is not one of a nonspecific protein reaction. Recently Straus and his associates[2] repeated the same experiments with slight modifications. One hundred and fifty-six female rabbits were separated into four groups, one being given "stimulating" doses of antireticular cytotoxic serum another "depressing" doses of antireticular cytotoxic serum, a third normal goat serum equivalent in volume to the "stimulating" dose of antireticular cytotoxic serum and the fourth normal goat serum in a volume equivalent to the "depressing" dose of antireticular cytotoxic serum. The extent of healing of the fractures was evaluated roentgenographically, by gross and microscopic examination of the tissue and by measuring the breaking strength of the line of union. The results indicated differences between the "stimulated" and "depressed" groups of animals and their respective controls. Statistical evaluation of the breaking strength of the healed fractures indicated significant differences between each of the groups and its control. The experiment was repeated on two additional occasions with similar results. The Los Angeles investigators conclude that stimulation of the healing of experimentally produced fractures in rabbits can be induced with small doses of antireticular cytotoxic serum and depression of healing with large doses, as claimed by the Soviet investigators.

ORGANIZATION SECTION

PROCEEDINGS OF THE CHICAGO SESSION

MINUTES OF THE SUPPLEMENTAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN CHICAGO, DECEMBER 9-11, 1946

HOUSE OF DELEGATES

First Meeting—Monday Morning, December 9

The House of Delegates convened in the Assembly Room of the building of the American Medical Association, 535 North Dearborn Street, and was called to order at 10:15 a. m. by the Speaker, Dr. R. W. Fouts.

Preliminary Report of the Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that 133 delegates had registered up to the present time. He requested the wishes of the House with respect to the seating of the delegate from the Section on the General Practice of Medicine, who was not provided for under the apportionment of delegates in effect at this session. On motion of Dr. Holman Taylor, Texas, seconded by several delegates and carried, the House voted to seat at this session the delegate from the Section on the General Practice of Medicine.

Roll Call

The Secretary called the roll and announced that a quorum was present.

Adoption of Proceedings of San Francisco Session in 1946

On motion of Dr. J. Stanley Kenney, New York, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the proceedings of the San Francisco session of the House of Delegates held in 1946 were adopted as printed.

Address of Speaker, Dr. R. W. Fouts

The Vice Speaker, Dr. F. F. Borzell, Pennsylvania, presided while the Speaker of the House read his address as follows, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker, Members of the House of Delegates and Guests:

It is again my privilege and distinct pleasure to call to order this body of distinguished workers. In so doing I desire to express my sincere appreciation for the implied confidence expressed by you in placing this responsibility on me.

That this House is composed of distinguished men with far reaching vision is evidenced by the many policies evolved during past years that are now serving to guide American medicine through the vicissitudes of these changing times. I bespeak for this session's activities a continuation of these principles and policies and a sober consideration of all questions presented at this session. I believe this to be the most important session held since I became a member of this House, which is more than a quarter of a century, as our actions today may set the pattern for the future of organized medicine. Let us approach each problem in a spirit designed for the purpose of accomplishing the greatest good for American medicine, as it affects our patients as well as ourselves.

Permit me to assure you again that it is your Speaker's untrammeled and unrestrained effort to see that the long established rules of procedure of the House are observed and carried out to the letter.

Your Speaker would again urge that more attention be given by the delegates to the hearings on the various resolutions by the respective reference committees. Far too often has a reference committee reported that only two or three, and sometimes no one, appeared to discuss pending resolutions.

Every delegate has the right to expect and will be given the privilege of the floor to ask a question or express his views on any matter pending before this House. May I urge that you be alert and exercise this privilege to the end that only the best possible results may obtain from our deliberations. Tremendous responsibilities rest with each and every delegate. Let us discharge these obligations in such manner as to reflect credit on every one concerned and obviate some of the criticism that has at times emanated from misunderstanding or the uninformed.

And now, conforming to precedent, it becomes my duty to request that we pause to pay tribute to those Fellows who have served in this House and whose life's activities have ceased since our last session. The list of names will be presented at our June meeting.

Reference Committees

In the selection of reference committees, your Speaker has again given consideration to the representation accorded each state on various Councils, Bureaus and the Board of Trustees. An earnest endeavor has been made to give just representation to every state.

The Speaker requested permission to appoint three additional reference committees, which was granted by the House. The personnel of all reference committees as appointed by the Speaker follows:

SECTIONS AND SECTION WORK

Wingate M. Johnson, North Carolina, Chairman.
Roy B. Henline, Section on Urology.
Jesse D. Hamer, Arizona.
Albert F. R. Andresen, New York.
Claude R. Keyport, Michigan.

RULES AND ORDER OF BUSINESS

Edward P. Flood, New York, Chairman.
James P. Kerby, Utah.
Mather Pfeiffenberger, Illinois.
Richard D. Simonton, Idaho.
William D. Stovall, Wisconsin.

MEDICAL EDUCATION

J. F. Hassig, Kansas, Chairman.
A. W. Adson, Minnesota.
Leland S. McKittrick, Massachusetts.
Alfred S. Giordano, Indiana.
Henry B. Mulholland, Virginia.

HYGIENE AND PUBLIC HEALTH

Don F. Cameron, Indiana, Chairman.
Thomas S. Cullen, Maryland.
Charles R. Rountree, Oklahoma.
Thomas K. Gruber, Michigan.
Thomas A. Foster, Maine.

LEGISLATION AND PUBLIC RELATIONS

Charles H. Phifer, Illinois, Chairman.
Thomas P. Murdock, Connecticut.
John J. Masterson, New York.
Lowell S. Goin, California.
Edward Jelks, Florida.

AMENDMENTS TO CONSTITUTION AND BY-LAWS

Allen H. Bunce, Georgia, Chairman.
K. S. J. Hohlen, Nebraska.
James Z. Appel, Pennsylvania.
Hugh P. Smith, South Carolina.
Edward H. McLean, Oregon.

REPORTS OF OFFICERS

John W. Cline, California, Chairman.
A R. McComas, Missouri.
James Q. Graves, Louisiana.
Ivan Fawcett, West Virginia.
Raymond L. Zech, Washington.

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Clarence G. Bandler, New York, Chairman.
Edgar P. McNamee, Ohio.
Guy W. Wells, Rhode Island.
James P. Wall, Mississippi.
L. J. Kosminsky, Arkansas.

CREDENTIALS

G. Henry Mundt, Illinois, Chairman
A P Nachtwey, North Dakota.
H. B Everett, Tennessee.
Charles F. Strosnider, North Carolina.
Raymond F. Peterson, Montana.

MISCELLANEOUS BUSINESS

William A Coventry, Minnesota, Chairman.
R B Anderson, Texas.
George A. Woodhouse, Ohio.
Warren L. Allee, Missouri.
William F Costello, New Jersey.

EXECUTIVE SESSION

Elmer Hess, Pennsylvania, Chairman.
William Weston, Section on Pediatrics.
J. B. Lukins, Kentucky.
Holman Taylor, Texas.
Deering G Smith, New Hampshire.
W. T. H Baker, Colorado.
Thomas F. Thornton, Iowa.

TELLERS

James Beebe, Delaware, Chairman.
John W. Green, California.
Theodore H. Harwood, Vermont.

SERGEANTS-AT-ARMS

Frank E. Reeder, Michigan, Chairman.
H. Russell Brown, South Dakota
Moreton J. Thorpe, Nevada.

MEDICAL SERVICE

Herbert H. Bauckus, New York, Chairman.
L. Howard Schriver, Ohio.
George P. Johnston, Wyoming.
Joseph H. Howard, Connecticut.
J. Stanley Kenney, New York.

EMERGENCY MEDICAL SERVICE

Walter G. Phippen, Massachusetts, Chairman.
C B Conklin, District of Columbia
Stephen E Gavin, Wisconsin.
George Braunlich, Iowa.
Grover C. Penberthy, Section on Surgery, General and Abdominal.
Arden Freer, U. S. Army.
John Harper, U. S. Navy.

Address of the President, Dr. H. H. Shoulders

The Speaker presented the President, Dr. H. H. Shoulders, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates:

It was with my entire approval that the decision was made that you would not hear an address from the President and the President-Elect, because such action would delay the proceedings of the House. But while I have the floor and may not get it again, I should like to take occasion to make two or three observations.

First I should like to observe that we are meeting now in a different atmosphere from that which existed in July and from that which has been in existence for quite some time. We now are in an atmosphere that approaches freedom—the freedom to go forward in the accomplishment of the great mission of medicine.

I have no suggestion with respect to change of fundamental policies. On the contrary, I think their usefulness and effectiveness and wisdom have been demonstrated in the crucible of time and experience, and fundamental policies should not be altered.

Second, there should be no let-up in our efforts to extend medical care as far as possible, and the adoption of new financial technics which will make it more available, probably—the financing of it at least—to people of moderate means.

I would make the observation also that my contact with the profession has been rather broad for me in the last six months, and I have formed the impression that the American Medical Association is not a weak organization but, on the contrary, is a strong organization. It is an organization with a past, a past of which we can be proud, and a future of which we can be hopeful.

Address of the President-Elect, Dr. Olin West

The Speaker presented the President-Elect, Dr. Olin West, who addressed the House as follows:

Mr. Speaker, I thank you for your very gracious reception. I was informed there were to be no speeches by the President and President-Elect. I will take time only to do one thing, and that is to commend especially the last sentence in the address delivered by Dr. Shoulders.

I have confidence that the American Medical Association, with all the progress that it has made, will continue to progress in its efforts to promote the art and science of medicine, in spite of any bickering, in spite of any destructive criticism. I believe that the profession and the public still have confidence in the American Medical Association, and I could give you many reasons for that belief.

I wish I could take enough of your time to tell you some of those reasons and to tell you of the progress that has been made and is being made today in carrying out the aims and objects of this Association as defined in its Constitution.

I hope the deliberations of this House at this session will contribute to further progress on the part of this organization, which, in my opinion, is the greatest of its kind in all the world.

I thank you.

REPORTS OF OFFICERS

Report of Board of Trustees

Dr. R. L. Senseních, Chairman, Board of Trustees, presented the following report of the Board of Trustees, a mimeographed copy of which had been distributed to each member of the House, and which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

To the Members of the House of Delegates of the American Medical Association:

The following ad interim report relative to the functions and activities of the various Councils, Bureaus and Departments of the Association is respectfully submitted. This will be augmented by a supplementary report to be presented personally by the Chairman of the Board of Trustees.

The Journal of the American Medical Association

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has now reached the highest point of circulation in its history, approximating over 130,000 weekly. The scope of its content is controlled to some extent by the shortage of paper and of personnel, but it now includes adequate presentation of practically every phase of the advancement of medical science and the interest in medical affairs. Recently THE JOURNAL has begun publication of portions of the "History of the American Medical Association" with a view to the publication of the complete work in book form in time for the Centennial Celebration.

Special Journals

The special journals of the American Medical Association continue to maintain leadership in their fields, but the Association Press has been greatly handicapped in recent months by a shortage of personnel and by labor regulations which greatly diminish the amount of time available for the services of the personnel at hand. Hence practically all of the special periodicals are appearing slightly late, and it is impossible to say, until difficulties with labor shall have been adjusted, when it will be possible again to restore these publications to their usual schedules.

Hygeia, the Health Magazine

During the past four years the circulation of HYGEIA, the Health Magazine, has been held down because of the shortage of paper. A year ago a small increase in paper tonnage was granted, so that for January 1946 it was possible to print 155,000 copies. The press run on the December 1946 issue was 192,000, and it is expected that beginning January 1947 a circulation of 200,000 or better will be maintained, depending on the supply of paper. HYGEIA is greatly in need of additional reading pages. As soon as feasible, it is hoped to increase the number of pages in each issue from the present 80 to 96 or 112 pages.

Most of the increased circulation of HYGEIA has been obtained from select fields, such as physicians, dentists, schools, libraries, nurses and health teaching groups. During the past year, exhibits have been presented at the annual conventions of the American Medical Association, the National Education Association, the American Nurses Association and the American Public Health Association.

Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau, established in 1913, was reorganized in December 1945 and had its most successful year (fiscal period December 1945 through November 1946). Net advertising sales exceeded $583,000 representing a gain of approximately $125,000 over the preceding year. Gross sales before agency discounts are estimated at $653,000. New and increased business written during 1946 exceeds $142,000. A good portion of the new business extends into 1947. The actual revenue disbursed to the thirty-five state medical journals that are members of the Cooperative Medical Advertising Bureau exceeded $583,000, from which the Bureau's actual operating expense amounting to approximately $20,000, or less than 5 per cent, was deducted.

Several meetings of the Advisory Committee to the Bureau were held during the year and all matters advocated have been complied with, including establishment of a monthly news bulletin to keep the journals informed of progress made and to provide helpful hints on advertising makeup, current listings of accepted products, notice of meetings and other pertinent facts.

Dr. Julian P. Price of South Carolina was elected as a member of the Advisory Committee to succeed Dr. John S. Bouslog of Colorado, whose term expires in December 1946. Dr. George F. Lull succeeded Dr. Olin West as member ex officio. The Bureau has been enlarged, and innovations and needed changes have been made in Bureau procedures. It is anticipated that the Cooperative Medical Advertising Bureau will continue to increase its value to the journals which it represents, from a remunerative as well as from an informative point of view.

Directory Department

The work of the Directory Department is to maintain a biographic record of the physician with his latest address, from which a directory of physicians can be published. There is also issued in this department, on the first and fifteenth of each month, a supplementary service to the Directory that lists the changes in the medical profession. Since the publication of the 1942 Directory, 34 018 names of new physicians have been added to the files, 113,726 changes of address have been recorded and 15,501 names have been dropped on account of death or for other reasons.

The work of the department has greatly increased because of the return to civilian practice of 55,000 medical officers who have terminated their service with the government. Some 40,000 of these physicians have been located and listed in the supplementary report service, but the other 15,000 have not been heard from or their mail has been returned marked "moved—address unknown."

As it has been more than four years since a Directory has been published, requests by telephone and mail for information about physicians have tripled. Requests for data on applications for membership in county medical societies, American boards of examiners in specialties and membership in special medical societies, along with letters from alumni associations to check addresses, make up a good share of this work. Inquiries are being received from men formerly in military service who are trying to locate physicians who treated them during the war in order to establish disability claims. In addition, a number of physicians are trying to locate other physicians they met while in the armed forces. Before the war three clerks handled requests for such information, now six are required.

The principal reason for the delay in publication of a new American Medical Directory is the shortage of clerical help, but the lack of labor in the printing department and the scarcity of paper also are factors.

Mailing and Order Department

The activities of the Mailing and Order Department have increased considerably during the past months. The rate of increase is about 22 per cent, although the increase in billing alone is almost 100 per cent. This unusual increase in billing orders resulted from a decision made late in 1945 that all orders from physicians on their formal letterheads were to be billed, whereas previously advance remittance was requested. The work of the department has been handicapped considerably by inability to obtain and retain adequate personnel and by the shortage of many book items.

Activities in the stock and shipping room likewise have increased.

The outgoing first and third class mail service has greatly increased in the past year as the result of the addition of new and the expansion of existing departments in the headquarters offices.

Council on Pharmacy and Chemistry

The Council on Pharmacy and Chemistry has continued its basic work of examining the merits of medicinal preparations. This includes editing and publishing the annual volume of New and Nonofficial Remedies and the Annual Reprint of the Reports of the Council, of answering inquiries of physicians and of cooperating with other headquarters offices. At the present time new editions of Useful Drugs, the Epitome of the U. S. P. and N. F. and the A. M. A. Interns' Manual are in preparation; the existing stocks of all these have been practically exhausted.

In addition, the Council has actively pursued the postwar expansion and reorientation of its activities. This is best epitomized in the proceedings of the Council's recent meeting on November 1 and 2. Preceding this meeting the Council held a conference with representatives of the pharmaceutical industry on the subject of the newly revised rules of the Council. The conference was characterized by a remarkable spirit of good will and cooperation sparked by a frank statement of the manufacturers' representatives on points of difficulty in application of the new rules. Full agreement was reached on all essential points, and the resulting modifications will be published in the near future. Incidentally, it may be remarked that the Council's office has been swamped with presentations of products from firms who are now striving to bring their policies into conformance with Council principles as well as from already recognized manufacturers of products which can now be made acceptable under the revised nomenclature rulings.

At the Council meetings which followed the conference with the manufacturers, the agreements reached in the conference were ratified and a further revision, or rather clarification, of the rules was authorized. The Council heard a report from Drs. Reed and Viehoever of the U. S. Department of Commerce on medical and pharmaceutical information obtained from German war records and agreed to receive and consider any further reports the Technical Industrial Intelligence Division might submit. In a discussion of the warnings required by the Food and Drug Administration to be placed by pharmacists on packages of Thiouracil prescribed by a physician, the Council considered the desirability of so amending the Federal Food, Drug and Cosmetic Act as to place solely with the physician the responsibility for issuing any needed warning in the prescribing of toxic products. It was agreed that physicians should be urged to a more lively appreciation of their responsibility in prescription and administration of drugs known to have inherent dangers for the patient. The Council considered the desirability of a report on the present status of the use of blood and blood derivatives and voted to consider, with a view to sponsorship, a report on this subject. The Council heard an informal report by Dr. Milton Veldee on the activities of the National Institute of Health in the consideration and licensure of biologic and other medicinal preparations and proposed the preparation of a statement on this and on the activities of the Food and Drug Administration for the information of the medical profession, the Council further authorized the preparation of a report on the present status of questionable vaccines. The Council considered the possibility of serving as advisory consultant to government departments and/or commercial agencies in the distribution of the products of atomic fission for experimental study or actual medical use. The Secretary was instructed to inquire as to what responsibilities the Council might be required to assume in giving such service. Considerable discussion was devoted to the subject of what medical agents might be safely advertised to the public. It was agreed to make further study of this question on the basis of reports to be prepared and presented on various classes of agents proposed for direct promotion to the public. The Council considered the feasibility of encouraging excellence in the exhibits of pharmaceutical manufacturers at the annual sessions of the Association and voted to ask the Board of Trustees to consider the presentation of suitable awards for exhibits especially noteworthy for scientific, research or informational interest. Further consideration was given to the dangers from the promotion and use of high potency vitamin D preparations in the treatment of arthritis, and a further report on the prescribing of massive doses of vitamin D in this and other conditions was authorized.

HEADQUARTERS STAFF

The staff is returning to prewar strength and at the present time consists of three medical men besides the Secretary, three laymen who carry on office routine and seventeen women who act as secretaries, stenographers, typists and file clerks and one who undertakes special literature research projects. However, the new and expanded activities of the Council will require further expansion of personnel, especially at the professional and secretarial levels.

The Therapeutic Trials Committee

The Therapeutic Trials Committee was formally organized in April with the appointment of a full time secretary. Requests for clinical investigations of several pharmaceutical products have already been received and acted on by the Committee. Steps have been taken to coordinate the work of the Committee with other agencies interested in research such as the National Research Council and the U. S. Public Health Service.

In order to provide maximum service to investigators and pharmaceutical houses, information on the interests of clinical investigators and on the available facilities for clinical research is being collected. So far nineteen institutions, medical schools and hospitals have been visited by the secretary, 89 deans, professors and other persons interested in clinical research have been interviewed and information concerning the interests of 311 clinical investigators has been obtained.

As an aid to clinical investigators and for the purpose of facilitating the rapid development of knowledge concerning new therapeutic agents and procedures, the possibility of holding conferences of research workers in certain fields in which investigations are proceeding simultaneously in various centers is being explored. Such conferences would be held only if there is a reasonable probability that such a meeting would facilitate the research and provide substantial benefit both to the investigators and to the medical profession.

Steps have been taken to prepare reports for publication dealing with general problems relating to the proper conduct of clinical research. One such report on "The Costs of Clinical Research" is scheduled for early publication.

The Chemical Laboratory

During 1946 the Chemical Laboratory assisted the Council on Pharmacy and Chemistry in the examination and preparation of tests and standards for a number of new drugs, such as demerol hydrochloride, furacin, benadryl hydrochloride, thiouracil, tridione, monocaine formate, monocaine hydrochloride, ethynyl estradiol, sulfathalidine and ceepryn.

Laboratory reports on dosage forms of a wide variety of U. S. P. and N. F. drugs were also prepared in connection with Council consideration. A partial list of such products includes aminophylline, bismuth subsalicylate in oil, delvinal sodium, diethylstilbestrol dipropionate, ephedrine sulfate, mannitol hexanitrate, pentobarbital sodium, sulfadiazine, epinephrine, aluminum hydroxide, diethylstilbestrol, niacinamide, phenobarbital, sulfathiazole, ascorbic acid, calcium levulinate, zephiran chloride and sodium dehydrocholate.

The problem of suitable standards for amino acid preparations has received much attention, and consideration of products such as amigen, protolysate, lactamin and parenamine is progressing.

The Laboratory has also been concerned with standards for natural estrogens from pregnancy urine.

Some new products currently before the Laboratory for examination are diethylstilbestrol dipalmitate, choline dihydrogen citrate, merodicein, aluminum dihydroxy aminoacetate, sodium *p*-amino-hippurate, *p*-amino benzoic acid and dicumarol.

Council on Physical Medicine

Among the problems considered by the Council in 1946, the following are representative:

The Council is prosecuting its survey of methods for artificial respiration which are being used by lay organizations, life-saving crews, the Coast Guard and police and fire departments. Since undertaking these surveys the Council has clarified several controversial aspects of artificial respiration. A research project to investigate in the laboratory various methods of artificial respiration has been supported by funds from the Board of Trustees. This research is being carried on under the direction of Dr. Andrew C. Ivy.

The Council voted to undertake the consideration of thermometry in the practice of medicine. The accuracy, efficiency, calibration and other problems related to clinical thermometers will be studied. The committee has been appointed, and this work is now going forward under the direction of Dr. George Morris Piersol.

Several ultraviolet lamps recommended for disinfecting purposes have been considered. In general, the claims advanced for the efficacy of these products are exaggerated. The Council has found it necessary to withdraw acceptance of one of the disinfecting ultraviolet lamps which had been on the accepted list.

The Council gave consideration to products for the relief of allergic hypersensitiveness. Several mattress and pillow covers were considered and accepted. A new product was placed on the market which was considered and accepted, namely a pillow made of glass fibers. This product competes favorably with pillows made of feather substitutes and, as a matter of fact, it may prove to be a widely used substitute for goose feathers as a filling for pillows.

Radon ointments (Alphatron Radon Ointment) has been marketed to the profession for the treatment of radiation injuries, skin diseases and rheumatism as well as other conditions. A report of rejection has been prepared jointly with the Council on Pharmacy and Chemistry. It is the opinion of the Councils that unwarranted, exaggerated and misleading claims are being made for the ointment. The investigation is being continued.

Ultraviolet irradiation of the blood: Although many therapeutic claims are made for the Knott Hemo-Irradiator, the chief claim is the alleged successful treatment of asthma. In the opinion of the Council, this device is not efficacious and does nothing which cannot be accomplished by simpler means.

In the course of the year the Council voted to adopt a seal which has a format comparable to the seals of the Council on Pharmacy and Chemistry and the Council on Foods and Nutrition.

Consultants on Audiometers and Hearing Aids: The article "Tentative Standard Procedure for Evaluating Percentage of Hearing Loss in Medicolegal Cases" has been released for publication. The revised audiogram chart was adopted and published. Dr. Hallowell Davis of Boston accepted appointment as consultant to replace Dr. Horace Newhart, deceased. Dr. Burt R. Shurly resigned. Six hearing aids were accepted and one was rejected.

Consultants on Contraceptive Devices: The "Minimum Requirements for Acceptability of Contraceptive Devices" were adopted by the Council and sent to manufacturers of contraceptive devices for comment and suggestion. The requirements were referred to THE JOURNAL for publication. Three devices have been submitted for consideration.

Consultants on Education: The consultants recommended that an American Board of Physical Medicine and a Section on Physical Medicine of the American Medical Association be established. Dr. George D. Wilson accepted appointment as consultant.

Consultants on Electrocardiographs: "Minimum Requirements for Acceptable Electrocardiographs" were compiled in rough draft and sent to six manufacturers of electrocardiographs for comment and criticism. The requirements are not complete and are still undergoing revision. One electrocardiograph has been submitted for consideration, but the report is not complete.

Consultants on Occupational Therapy: The "Manual for Occupational Therapy" has been revised and released for publication. It will be ready for distribution Jan. 1, 1947.

Consultants on Ophthalmic Devices: An article entitled "What Is Orthoptics" (first paper) has been published. Consultants have voted to sponsor articles on contact lenses, artificial eyes and orthoptics (second paper). Articles on contact lenses and orthoptics are being considered at the present time.

Consultants on Respirators: Three respirators have been submitted for consideration. They are undergoing investigation at the present time.

Consultants on Roentgen Rays and Radium: A joint meeting of the Consultants on Roentgen Rays and Radium and the Consultants on Atomic Energy with the Council on Industrial Health and the Council on Physical Medicine is called for Dec. 12, 1946. The present status of the therapeutic efficacy of radium, radon and radioactive isotopes will be discussed and an outline of the Council's future activities in these fields will be proposed. On the agenda will be the compilation of requirements for acceptance of radium, radon and radon products.

The lack of raw materials and the labor shortage have restricted the output of physical therapeutic appliances. Appliances are being sold, but in most instances the firms have not been able to supply the demand. For the most part these appliances are made according to the specifications of formally accepted apparatus.

The successful employment of physical medicine during World War II has had a great influence on the acceptance of physical medicine by the general practitioner. As a result, physical medicine has gained in stature.

Council on Foods and Nutrition

The basic work of the Council on Foods and Nutrition has to do with its food acceptance program and nutrition education. In this report are enumerated the services and programs now in effect which were initiated before Jan. 1, 1946, those initiated during 1946 and those authorized or contemplated at the meeting of the Council in November.

The services and programs initiated before Jan. 1, 1946 which are still in effect and being continued are (1) the study of new food products for possible Council acceptance; (2) the review of all food and nutrition advertising copy; (3) the review of general educational advertising; (4) the conduct of the vitamin D milk program, which involves fluid, evaporated and dried milks; this requires the review of assays on each accepted product and the checking of a large number of labels and advertisements for accuracy of statement; (5) the conduct of a program aimed to encourage the production of fruit juices with a high natural level of vitamin C; (6) the iodized salt program; (7) the flour enrichment program; the Council led in the early shaping of public opinion relative to this program; (8) the corn enrichment program; (9) the preparation of Council reports and Council sponsored reports on problems of food and nutrition in health and disease; the Council believes that expansion of this program would be of value; (10) the preparation of replies to letters of inquiry; (11) the conduct of an informal consultation service relative to food and nutrition problems; (12) book reviews and critical reviews of pertinent subjects; the Council office hopes to supply more of these.

The services, programs and studies initiated in 1946 are as follows: 1. All foods bearing the Council seal that were accepted more than two years ago are being restudied and reconsidered. 2. The vitamin D milk program has been brought up to date. 3. The Council's booklets "Rules" and "Decisions" are to be revised. 4. A protein hydrolysate committee was appointed to work with a similar committee from the Council on Pharmacy and Chemistry. 5. A study interrupted by the war of the methods of ice cream manufacture and its role in nutrition is to be continued. 6. The importance of sanitary measures in cheese manufacture is to be studied. 7. Methods of evaluating foods as sources of vitamins and minerals are to be studied. 8. Data on the subject of nutrition teaching methods and objectives in schools of medicine are to be procured. 9. In cooperation with the Bureau of Health Education, the Council is developing a series of radio broadcasts on the subject of foods and nutrition. 10. As part of a program to increase interest in nutrition, the Nutrition Foundation has consented, at the suggestion of the Council, to make *Nutrition Reviews* available gratis to the fourth year students of a selected group of medical schools. 11. Ways and means of increasing the usefulness of the Council to the medical student, the physician and the public are to be studied.

The services and programs authorized or studied at the meeting of the Council on November 21 are (1) a report to the Board of Trustees on the subject of iodized salt, (2) the development of scientific exhibits, (3) revision of the Handbook on Nutrition, (4) the role of beverage bases, (5) the problem of standards for baby foods, (6) a pilot study of the methods and effectiveness of nutrition education in a small group of medical schools, perhaps among the most important of the proposed studies, is to be conducted by Drs. Elvehjem and Youmans and the Secretary of the Council and (7) a cooperative effort with the Pediatric Research Society in the preparation of nutrition teaching aids for pediatrics.

The responsibilities of the Council have increased as the need for new services has become apparent. The present staff is inadequate to accept the challenges being offered at the present time. The Council needs the continued interest and support of the Association in all these projects because they are vitally concerned with nutrition in health and disease.

Council on Industrial Health

Principal developments since the last report of the Council on Industrial Health have been as follows:

PUBLIC RELATIONS

World Health Organization.—Information is not yet available regarding the status of industrial hygiene in the proposed World Health Organization. In all likelihood a mixed committee will be appointed consisting of public health experts, representatives of the International Labour Office and of the World Health Organization itself to consider matters of social insurance and industrial hygiene. Meanwhile the United Nations organization is establishing itself in New York and is setting up a health program for its employees, who will likely number about two thousand.

The International Labour Office.—This has reestablished its medical division under the direction of Dr. Marcos Charnes of Chile. The medical activities, which included valuable bibliographic services, were discontinued as a result of the war. Conferences have been held with the director of the safety division of the International Labour Office, which has already been reestablished in Geneva.

Pan American Relations.—On approval of the House of Delegates, conferences with representatives of Canada and of Latin American countries have indicated the great desirability of regular discussion of industrial health developments in these countries, perhaps by establishing an annual or biennial Pan American Industrial Health Congress.

Public Law 658 Enacted by the Seventy-Ninth Congress.—This is an act to provide for health programs for government employees, restricted essentially to preemployment and periodic physical examinations, control over working environment and health counseling. Members of the Council on Industrial Health had previously appeared at hearings in favor of this bill if necessary safeguards were incorporated.

The Division of Industrial Hygiene in the U. S. Public Health Service.—This has been reorganized for improved efficiency of its field activities and states relations and to reestablish research facilities in the division itself. In current appropriations for the U. S. Public Health Service, funds are for the first time specifically earmarked for industrial hygiene services.

American Management Association.—A meeting has been held with the president of the American Management Association. It is expected that a useful working relationship can be developed with this organization, particularly in educational work among industrial firms not large enough for full time medical services.

National Bituminous Coal Mines Wage Agreement.—The Council has been particularly interested in the medical implications of the National Bituminous Coal Mines Wage Agreement. Since the last meeting of the House of Delegates, representatives of the Council on Industrial Health and the Council on Medical Service have participated in conferences at Williamson, W. Va., and in Washington, D. C. Visits of inspection have also been made in the coal mines area with the survey teams assigned by the U. S. Navy. The Council on Industrial Health has been particularly interested in the absence of industrial health services in the soft coal mines and has brought this fact to the attention of the surveying groups on several occasions. The factors of general medical care, including prepayment plans for medical services and hospitalization, have been the particular problem of the Council on Medical Service.

The Coal Mines Wage Agreement strongly suggests that health and welfare will be important factors in all future collective bargaining. It is difficult to predict in what manner and to what degree the conventional methods of industrial medical service will change. The Council on Industrial Health feels that herein lie many opportunities for constructive medical leadership.

Medical Services Operated by Labor Unions.—In consideration of greater labor participation in industrial medical affairs, the Council expects to bring up to date its information about existing medical services operated by labor unions.

PROFESSIONAL RELATIONS AND SERVICE

The Seventh Annual Congress on Industrial Health.—This was conducted in Boston Sept. 30-Oct. 2, 1946 with the Massachusetts Medical Society and the Council of the New England State Medical Societies as cosponsors. The meeting was regarded as one of the most successful congresses yet conducted and convinced the Council that future meetings of this kind should be held in various parts of the country instead of exclusively in Chicago as heretofore. These congresses bring important developments in the field of industrial medicine, surgery and hygiene to the attention of the profession at large and demonstrate to physicians the great opportunities for medical service that lie in the industrial health field.

Field Activities.—These have continued and the Council staff has participated in several regional conferences on industrial health. In these field services the Council strongly upholds the principle that professional standards are a prerogative of physicians in industry, that these standards must be based on scientific and ethical principles and that medical progress in the field must depend on good medical education and medical organization.

Since it is important to acquaint the public as well as industry with the considered point of view of the profession along these lines, a speakers' bureau is being organized with volunteer speakers from all the principal industrial areas.

Professional Education and Placement.—Opportunities for professional training in industrial health are steadily improving in such centers as Wayne University, Yale University, New York University, Columbia University and Long Island College of Medicine. The demand for qualified physicians in industry has held up remarkably well in the early postwar months; in fact, the demand exceeds the available supply. Medical veterans and others who are interested in industrial medicine as a career are using the Council's placement service in substantial numbers. In general, requests received from industry for qualified medical assistants are referred to a county medical society secretary or industrial health committee in the hope that the place can be filled locally. If not, names of applicants on file are supplied.

Status of the Section on Preventive and Industrial Medicine and Public Health.—The status of this section has been a matter of concern to the Council as well as to many practitioners in these fields. The Council therefore recently resolved that the best interests of the medical profession can from this point on be more effectively served by a separate Section on Occupational Health and Medicine and that the proper authorities in the American Medical Association be requested to take this matter under advisement.

SCIENTIFIC DEVELOPMENT

Aluminum Prophylaxis and Therapy in Silicosis.—A joint conference was held on October 31 with the Council on Pharmacy and Chemistry and its Therapeutic Trials Committee regarding the present status of the prevention and treatment of silicosis with aluminum. The position taken was to the effect that use of aluminum for these purposes is still in the experimental stage, that continued competent observation over a long period is necessary to assay treatment adequately and that there should be no curbs placed on continued research and investigation.

Atomic Energy.—The Council is deeply interested in the organization of the Board of Consultants on Atomic Energy under the sponsorship of the Council on Physical Medicine. Since it is proposed to use nuclear energy in industry as a source of power, the question of occupational risk is of considerable importance. A symposium on atomic energy in industry and medicine under the joint auspices of the Council on Physical Medicine and the Council on Industrial Health was an outstanding event of the Seventh Annual Congress on Industrial Health.

WORKMEN'S COMPENSATION

The National Conference Committee on Workmen's Compensation.—This committee has been active during recent months. Those activities affecting medicine particularly have been largely assigned to the Council on Industrial Health for primary investigation and report. These deal with reform in medical testimony, disability evaluation, rehabilitation, elevation of standards of medical care for the industrially disabled and greater participation in workmen's compensation administration by medically trained people with essential qualifications. The Council is represented actively on other subcommittees dealing with the simplification and uniformity of report forms and the adoption of a standard nomenclature and uniform statistical methods. Other subcommittees of the National Conference Committee on Workmen's Compensation are paying particular attention to administrative details such as prompt payment of compensation benefits and reduction in hearings and appeals. Each subcommittee is empowered to seek technical advice and assistance from other interested groups. The Council has taken advantage of this provision and sought help from physicians and others especially equipped to assist in the necessary groundwork. These reports will be presented to the parent organizations of the participants for additional study and, if necessary, ratification.

The work of the National Conference Committee was reviewed at the recent convention of the International Association of Industrial Accident Boards and Commissions. Representatives of the Council attended and participated in a symposium on medical service in workmen's compensation.

HEADQUARTERS STAFF

Dr. H. R. Hennessy has joined the staff of the Council to maintain close relations with committees on industrial health in the state and county medical societies and with other professional groups in the field having important interests in industrial health.

The Council has obtained the services of Capt. E. W. Brown, recently retired from the Medical Corps of the U. S. Navy, to act as executive officer for the Council's Committee on Scientific Development. He will make regular evaluations of industrial medical education and research, develop a clearing house on industrial hygiene and toxicology, and work closely with the committees on industrial health which have been set up in the sections of the Scientific Assembly.

Bureau of Health Education

The general work of the Bureau of Health Education proceeds with normal evidences of growth. The present personnel of the Bureau consists of a Director, an Associate Director, a Medical Consultant in Health and Physical Fitness, an Educational Consultant in Health and Physical Fitness and secretarial and clerical assistants. The two Consultants in Health and Physical Fitness were added to the staff August 16 and September 16, respectively, as authorized by the Board of Trustees.

Correspondence

The general correspondence of the Bureau with cooperating lay organizations, health departments, physicians and medical societies is well in excess of 5,500 units, which will establish a new high for the Bureau. Included with a majority of the replies was literature dealing with a wide variety of physical disorders. This literature is being constantly revised and added to as a means of keeping it abreast of new developments in medicine and surgery. More than a thousand inquiries were referred to the Bureau from health education exhibits in the Cleveland Health Museum, the Newark Health Museum and the Chicago Museum of Science and Industry and as a result of health exhibits at various state or national medical and public health meetings.

Loan Collections

Seventy-six loan collections were sent out by the Bureau. This represents a slight increase over the previous year. It is noted that requests for these loan collections are being received in increasingly larger amounts from lay individuals with special scientific training. Proportionately, requests from physicians are decreasing. It would appear that the latter development has been the result of increased service on the part of state and county medical societies, many of which now have a large amount of this type of information available to physician members.

Radio Broadcasting

Radio broadcasting was begun in January 1946 on the NBC network under the title "Doctors at Home" and continued for twenty-six weeks. It proved to be the most successful series thus far broadcast in the twelve years of dramatized broadcasting. In addition, physicians broadcast talks on three nationwide networks and on all radio stations in San Francisco during the annual session.

Negotiations have been begun with other networks with a view to placing programs on them as well as on NBC. Thus far one promising attempt with CBS has failed, but the situation is by no means unfavorable for success along several lines, including CBS.

Electrical Transcriptions

Electrical transcriptions have continued to form a major part of the Bureau's activity. It is estimated that during 1946 there will be a total of more than 350 series lent, with local broadcasts numbering between 4,000 and 4,500 on approximately 120 outlets, mostly those not reached by network programs.

Television

On April 2, 1946 the first of a series of television programs was presented by the Bureau of Health Education over Station WBKB, Balaban & Katz, Chicago. A statement heralding this pioneer venture in health education appeared in the March 23 issue of The Journal. The possibilities cited in that statement have materialized much as was forecast. Acceptable technics have been worked out with the active cooperation of the television station personnel. It has been found possible to integrate dramatization, sections from available motion picture films and discussions by physicians, specialists or otherwise, into acceptable programs that are believed to present health lessons in an extremely forceful manner. It is expected that further refinements in technic will be developed as the Bureau continues this activity as a public service contributed by Station WBKB.

Full Time Public Health Units

In accordance with instruction received from the Board of Trustees, the Bureau sent a circular letter to all state medical societies calling their attention to the resolution passed by the House of Delegates some time ago advocating the establishment of county, joint county or district public health units on a full time standardized basis for the entire continental United States.

Replies have been received from Wisconsin, Illinois, Nevada, Michigan, Maryland, Vermont, Missouri, Indiana, New Mexico, Tennessee, New York and Alabama. In most instances these states were already on record with their own resolutions supporting the resolution of the House of Delegates. Only one county in one state gave evidence of active opposition to the idea.

Mental Hygiene Work by State Medical Societies

As instructed by the Board of Trustees, the Bureau sent a circular letter to state medical societies calling their attention to the resolution about the importance of mental hygiene work by state medical societies.

Replies have been received from Hawaii, Kansas, Texas, Washington, Florida, Colorado, Wyoming, Minnesota, New York, Tennessee, North Dakota, Michigan, Nebraska, Nevada, Wisconsin, Kentucky, Alabama, Connecticut, the District of Columbia and Indiana. In most instances the information contained in these letters indicated that the state medical society already had a committee on mental hygiene. Some of these committees have been functioning actively for many years.

Health and Physical Fitness Program

A source file is being prepared which already includes materials on school health and physical education from thirty-eight states and many professional and nonprofessional organizations.

The consultants have reviewed material and made suggestions for two state groups concerned with curriculum planning in health and physical education.

An outline has been prepared for the revision of "Health Inspection of School Children," which will be submitted to the Joint Committee on Health Problems in Education of the American Medical Association and the National Education Association for approval and subsequent development for publication.

A report of the National Committee of the National Conference for Cooperation in Health Education, "The Functions and Education of Health Personnel in Relation to the School Health Program," has been reviewed by the consultants previous to its publication.

The consultants, with the approval of the Board of Trustees, have accepted invitations to membership on the National Committee on Standards for Interscholastic Athletics of the American Association for Health and Physical Education and the National Committee on Standards and Surveys on Health Education of the American Association of Teachers' Colleges.

A series of thirteen radio transcriptions on physical fitness have been prepared for use by county medical societies or by other groups having the approval of the medical societies, in the promotion of physical fitness.

A television program on physical fitness was broadcast over station WKBK November 7, and a second is contemplated for late December.

The consultants have served as participants or have given talks at health conferences or other group meetings in Arizona, Illinois and Wisconsin and have other assignments of this type scheduled. Articles on health and physical fitness have been submitted to professional journals on health, physical education and recreation. Each of the consultants has been invited to prepare and is working on one chapter of the revision of "Health Education," published by the Joint Committee on Health Problems in Education. A considerable amount of correspondence addressed to the American Medical Association on health and physical education topics has been referred to and answered by the consultants. The consultants prepare each month a series of "Suggested Discussion Topics" for the classroom use of Hygeia, the Health Magazine, in secondary schools.

Pamphlets

Reacting to the justified criticisms of the Bureau's pamphlet publications contained in the Rich Report, an experimental project has been started in the Bureau to make evaluations of the pamphlets. Evaluation by a lay reader is more significant than by a doctor, since it is for lay readers that these pamphlets are intended. A recommendation has been made to the Board of Trustees that the pamphlet publications of the Bureau be improved, as recommended by the Rich Report, through the appointment of a pamphlet editor whose full time and sole duty it shall be to evaluate pamphlets, make layouts, procure art work and keep the reprint stock constantly fresh and vital.

Cooperative Relationships

The Director, Associate Director and Health Consultants represent the American Medical Association on a number of committees, of which the most active ones are:

Health Education Committee of the American Cancer Society.
National Congress of Parents and Teachers.
American Public Health Association (several committees).
National Committee for Boys and Girls Club Work (4-H Clubs).
U. S. Children's Bureau, Advisory Committee on Maternal and Child Health.
Cook County Health Survey.
National Committee on Standards for Interscholastic Athletics of the American Association for Health and Physical Education.
National Committee on Standards and Surveys on Health Education of the American Association of Teachers' Colleges.

Bureau of Legal Medicine and Legislation

Since the last report of the Bureau was submitted, the 79th Congress has adjourned sine die. All legislation then pending died. The 80th Congress will convene in regular session early in January and it can reasonably be anticipated that much of the legislation pertaining to the field of medicine which failed of enactment in the last Congress will be reintroduced.

As a result of the November elections there will be a change in the chairmanships of Congressional committees generally, and those committees to which proposals relating to medical care are customarily referred will therefore be under new leadership. It is reported that Senator Taft of Ohio will head the Senate Committee on Labor and Public Welfare, as the former Committee on Education and Labor will be designated under the reorganization act. To this committee will probably be referred any new version of the Wagner-Murray-Dingell bill unless provision is made in it for the imposition of taxes, in which case the new version will go to the Senate Committee on Finance. Senator Butler of Nebraska has been mentioned as the new chairman of that committee, succeeding Senator George.

In the new setup of the House of Representatives, Congressman Knutson of Minnesota has been mentioned as the new chairman of the House Committee on Ways and Means, Congressman Cole of New York as the new chairman of the Committee on Education and Labor, and Congressman Wolverton of New Jersey as the chairman of the Committee on Interstate and Foreign Commerce, the three House committees to which are normally referred major legislation proposing health programs.

With the change in the political flavor of the Congress, it would seem reasonable to anticipate even more sober deliberation in connection with any proposals that may be advanced to revolutionize medicine.

The Hospital Survey and Construction Act.—The President approved this far reaching law on August 13. While it authorizes an appropriation of $3,000,000 for state conducted surveys and $75,000,000 annually for five years for construction purposes, the 79th Congress actually appropriated only $2,350,000, earmarked for assistance to states in surveying and planning and for the administrative expenses of the Public Health Service in connection with the program.

Preliminary procedures have been developed to carry out the provisions of the new law. On a federal level there has been created in the Bureau of States, United States Public Health Service, a Division of Hospital Facilities which will be responsible for carrying out the functions which the Public Health Service is authorized under the law to perform. A Federal Hospital Council has been appointed. An Advisory Committee has been formed the members of which will act as consultants to the Council and to the Surgeon General of the Public Health Service.

On a state level, twenty-nine states have enacted legislation designating a single state agency to function in connection with the program. In the majority of these states the state health department was the agency designated.

Growing out of this federal law is a movement to promote the enactment of uniform state hospital licensure laws. The Hill-Burton law does not require a participating state to enact a hospital licensing law. It does require the enactment by July 1, 1948 of legislation providing that compliance with minimum state standards of maintenance and operation shall be required in the case of hospitals which receive federal aid under the law. It is apparently felt that this requirement can be more readily complied with by the enactment of a state licensing law in which provision is made for adequate standards and through the mechanics of which such standards can be successfully enforced. A draft of a proposed state hospital licensing law is being formulated under the sponsorship of the Council of State Governments. The Association was asked to participate in perfecting this draft and that invitation was accepted.

Enlarged Federal Cancer Program.—The 79th Congress made available to the Public Health Service an increased appropriation to assist states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate public health services. Of this increase the sum of $2,500,000 has been earmarked by the service for grants-in-aid to the states for a cancer program. This program, apparently, will be similar to the existing programs for venereal disease control and for tuberculosis control.

Maternal and Child Welfare.—While Congressional action was not completed on the Pepper maternal and child welfare bill, additional funds were made available by the 79th Congress for grants to states for maternal and child health services—the authorization being increased from $5,820,000 to $11,000,000, for services for crippled children—the authorization being increased from $3,870,000 to $7,500,000, and for child welfare services—the authorization being increased from $1,510,000 to $3,500,000.

National Mental Health Act.—On July 3 the President approved the National Mental Health Act to provide, through the United States Public Health Service, for research relating to psychiatric disorders and to aid in the development of more effective methods of prevention, diagnosis and treatment of such disorders. This law authorizes an annual appropriation of $10,000,000 to carry out its purposes through grants-in-aid and otherwise. It also authorizes an appropriation of $7,500,000 for the erection and equipment of hospital and laboratory buildings and facilities in or near the District of Columbia, to be known as the National Institute of Health. While these authorizations are included in the enacted law, actually no sums were appropriated by the 79th Congress, and the activation of the program must therefore await further Congressional action.

The President's Reorganization Plan No. 2.—This plan became effective July 16 after the Senate had rejected a House concurrent resolution proposing that the Congress disapprove it. By it the Children's Bureau, the Division of Vital Statistics and the activities of the United States Employees' Compensation Commission were transferred to the Federal Security Agency. There the Children's Bureau was placed in an operating branch designated as the Social Security Administration, headed by Arthur J. Altmeyer. The Division of Vital Statistics was placed in an operating branch designated as Public Health, headed by Surgeon General Thomas Parran of the United States Public Health Service. The activities of the former United States Employees' Compensation Commission which was abolished by the plan were assigned to an operating branch designated as Office of Special Services to be carried on by a newly created Bureau of Employees' Compensation and an Employees' Compensation Appeals Board, this operating branch to be headed by Mrs. Jewell W. Swofford, former chairman of the United States Employees' Compensation Commission.

Other Federal Laws Enacted.—During the closing days of its 79th session, the Congress completed action on the following additional measures of interest to medicine: (1) a bill to provide for health programs for government employees; (2) a bill to authorize the Veterans Administration to employ, without affecting their retired status, retired medical officers to act as superintendents and directors of medical services in veterans' hospitals; (3) a bill to make permanent the act of July 11, 1941 prohibiting prostitution in the vicinity of military and naval establishments; (4) the Crosser bill to amend the Railroad Retirement Acts and the Railroad Unemployment Insurance Act providing, among other things, cash sickness and maternity benefits for railroad employees and (5) a bill to provide assistance to the states in the establishment, maintenance, operation and expansion of school lunch programs.

State Legislation.—A summary survey of state laws of medical interest enacted during 1946 was completed by Mr. George E. Hall, a Bureau staff member, and published in The Journal of August 31. Similar surveys will be made in the future and published in The Journal so that trends in medical legislation may be followed and so that each state medical association will be advised as to the types of medical laws enacted in each other state.

Taxes.—Conferences have been held with the technical staff of the Joint Committee on Internal Revenue Taxation with respect to two specific matters: (1) the elimination of the requirement that the tax imposed on physicians by the Harrison Narcotic Act be paid by a certified check if it is paid by check and (2) a proposal that members of professional groups which under state law cannot engage in corporate practice be permitted to take advantage of the lower corporate tax rates. These matters will be given continued consideration.

Miscellaneous.—The Director of the Bureau participated in a Seminar in Legal Medicine, held under the auspices of the Department of Legal Medicine, Harvard Medical School, October 21 to 26, and has accepted such speaking engagements as the pressure of other demands has permitted. Much time has been devoted to the preparation of a history of the Bureau for incorporation in the history of the American Medical Association being written in connection with the centennial celebration to be held in 1947.

Bureau of Medical Economic Research

At its September 1946 meeting the Board of Trustees changed the name of this Bureau, established in 1931, from the Bureau of Medical Economics to the Bureau of Medical Economic Research. The Board also announced the appointment of Frank G. Dickinson, Ph.D., as the new Director of the Bureau, succeeding Dr. R. G. Leland. The Board also stated that the Bureau would be reactivated and expanded and that research would be stressed.

Dr. Dickinson resigned his position as associate professor of economics at the University of Illinois, where he had taught economics since graduation in 1921 except for the school year in 1922-1923, when he was instructor in economics at the Pennsylvania State College. He also received his A.M. degree at the end of that year. He received his Ph.D. degree at the University of Illinois in 1927. His principal fields of study and teaching were insurance and statistics. He had served as president of the American Association of University Teachers of Insurance during 1944 and 1945.

In reactivating the Bureau it has been necessary to add to the economic books, pamphlets and bulletins needed for research. Building a library requires a good deal of time. The new director has studied the previous publications of the Bureau and desires to report that he regards them as extremely fine studies. Every week a number of these are mailed in answer to the numerous and varied queries received. He has worked in close cooperation with the Council on Medical Service, attending its meetings and being a member of its Subcommittee on Cooperation with Insurance Industry in the Development of Prepayment Medical Care Plans and of its Committee on Rural Problems on Medical Care Insurance. The Director addressed the Association of Medical Care Plans at its first annual meeting in October and attended the meeting of its Commissioners in Omaha, November 14 and 15. It is hoped that this organization and the Director of the Bureau working with the Council on Medical Service will be able to develop comprehensive actuarial data on the operations and possible expansion of the different medical care plans in the various states. It will probably be necessary to employ an actuary in the Bureau to perform this function efficiently. An actuary is also needed to help with some of the research program planned by the Bureau.

The staff operating the I. B. M. equipment at Association headquarters was transferred to the Bureau in September, and the Director has devoted a considerable portion of his time to reorganizing this group. He found that the punch card inventory was not adequate and that some pieces of equipment were lacking. The Bureau has been called on to furnish information for several agencies, including the Coal Mines Administration in Washington. This information could not have been furnished without the I. B. M. equipment. It should be stressed that for the most part the Bureau in this capacity acts as a service agency for the Councils at American Medical Association Headquarters, especially the Council on Medical Service and the Council on Medical Education and Hospitals, and for local and state medical societies. Routine work connected therewith has taken a good deal of the Director's time.

So far as staff is concerned the only major change is the addition of Mrs. Laurie Wallach as research assistant. The Board of Trustees has authorized the Director to employ a young Ph.D. in Economics and Statistics and an M.D. with an interest in the field of medical economics. The Director has not yet found any one for either one of these positions.

Research work, almost completed by Dr. Leland, for the preparation of a life table for physicians which will be presented at Atlantic City by the Statistical Bureau of the Metropolitan Life Insurance Company has been continued. A later study of deaths among physicians during the war period has been started and it is hoped that a fairly comprehensive picture of mortality among physicians during the whole war period can be presented. This study will not be completed before 1948.

The Director has observed that the studies made here and elsewhere on the supply of medical service use county data: that is, the population of a county is divided by the number of physicians in that county, and this ratio is called the physician-population ratio. Economic data do not follow county boundary lines, although the county may be an excellent unit for organizing a professional society. A physician is not a county coroner, and his patients often reside outside the county. The accessibility of medical service has undergone many changes in the last generation, and a study of the supply of medical service must recognize the changes wrought by hard roads and other improvements in transportation. Hence the Bureau is attempting to develop medical service areas which cut across county boundary lines and circumscribe the area served by the physicians in the community. These physician-population ratios for medical service areas, when completed, will indicate the actual supply of medical service to the people in all sections of the United States. It is estimated that it will require at least two years to mark out the entire map of the United States into medical service areas as has been done for retail trading areas by several research organizations. A questionnaire has been sent to the county medical societies which asks the respective secretaries to draw on a state highway map a line around the area served by the physicians located in the medical center of the county. The Bureau hopes that the answers to this questionnaire by the county societies' secretaries will be helpful in preparing the medical service areas of each state.

The Bureau does not yet have the staff necessary to revise all the bulletins published heretofore by the Bureau, but letters have been received from the deans of most of the colleges of medicine regarding revisions of bulletins used in the teaching of courses in medical economics. It is hoped to complete these revisions during 1947.

The Director was asked by the General Manager to assist the Committee on National Emergency Medical Service in the preparation and mailing of a postwar questionnaire to 50,000 discharged medical officers and to code, tabulate and analyze the returned questionnaires. This work has taken most of the Bureau's time during November and December. The response to the questionnaire is remarkably good. Probably 20,000 or more questionnaires will be studied by the Bureau and the report filed with the Committee in April.

The only writing which the Director has found time to complete is the first article in the January issue of Hygeia. The article represents the general philosophy of the new Director of the Bureau regarding the "Quest for Health." It is the opportunity to study this quest for health which induced him to follow the suggestion of his family physician, Dr. Glen R. Ingram of Champaign, Ill., late in July that he consider the position of Director. Without the suggestion and urging of Dr. Ingram the Director would never have known of the magnificent opportunity which the position of Director of Medical Economic Research has opened up to him in the four months he has been at American Medical Association headquarters.

Bureau of Exhibits

The first postwar year saw the resumption of normal activities in the Bureau of Exhibits, with expansion of the work in several lines. The personnel of the Bureau which had consisted of three persons for many years, was increased to seven, and additional space on the fourth floor of the headquarters building was obtained.

The activities of the Bureau fall into several divisions, as follows: The Scientific Exhibit at the annual session of the Association; Association exhibits, which include medical exhibits for medical meetings and other scientific groups, as well as health exhibits for fairs and expositions; motion pictures. Each of these subjects is discussed separately in this report.

The Scientific Exhibit

The Scientific Exhibit at the San Francisco session was held in the Civic Auditorium, occupying several small halls and corridors on the first and second floors. The exhibits dramatized the advances made in medicine during the war years, constituting an intensified course in graduate medical instruction.

Section Exhibits.—Active cooperation was maintained with the seventeen sections of the Scientific Assembly, each of which appointed representatives to the Scientific Exhibit.

The section representatives rendered valuable assistance to the Committee on Scientific Exhibit in securing exhibits of exceptionally high caliber and in giving freely of their time and energy throughout the year.

United States Army.—It was the desire of Surg. Gen. Norman T. Kirk, United States Army, to portray at the San Francisco session advances that medicine had made during World War II. The Army built the exhibit entirely new for the meeting. Other activities of the Army included participation in the Special Exhibit on Physical Medicine and maintenance of two motion picture theaters in the Veterans Building. The Committee on Awards issued a citation of Merit to the United States Army for these contributions.

United States Navy.—The United States Navy presented a spectacular group of exhibits and, in addition, the Navy participated in the Special Exhibit on Physical Medicine and showed a group of motion pictures in the Veterans Building. The Committee on Awards issued a Citation of Merit to the United States Navy for these contributions.

Special Exhibit on Fractures.—This feature of the meeting was presented for the fifteenth time over a period of twenty years. Except for the first two years, Dr. Kellogg Speed, Chicago, has been chairman continuously, and it is due to his initiative and energy that interest has been maintained. Continuous demonstrations were conducted in six booths to audiences that strained the facilities of the area to accommodate them. A pamphlet was prepared for distribution.

Special Exhibit on Physical Medicine.—This exhibit was shown for the first time at the San Francisco session and was under the guidance of Dr. Frank H. Krusen, Rochester, Minn., chairman. The exhibit included physical therapy, occupational therapy and rehabilitation, occupying twelve booths. Motion pictures were shown continuously in a room adjoining the exhibits. A pamphlet was prepared for distribution by the Committee, while numerous pamphlets from other sources dealing with various phases of physical medicine were likewise distributed.

Motion Pictures.—Motion pictures in the Scientific Exhibit were not shown in exhibitors' booths because of the problem created in congestion of the aisles; therefore special theaters were arranged where the audiences could be seated in comfort. There were six motion picture theaters, one in the Civic Auditorium and the other five in the Veterans Building, three blocks distant. Authors were encouraged to comment on their films as they were shown or to make remarks immediately before or after the showing.

Committee on Awards.—The Committee on Awards consisted of Dr. O. P. J. Falk, St. Louis, chairman; Dr. H. J. Corper, Denver; Dr. Leo F. Rigler, Minneapolis; Dr. Curtice Rosser, Dallas, Texas, and Dr. J. Ross Veal, Washington, D. C. All the members worked conscientiously and diligently over a period of three days, including two night sessions, and returned a report that received much commendation.

Twenty-three awards were presented: six medals, six certificates of merit, eight honorable mentions, two citations of merit and one special commendation. In addition, the Committee extended itself beyond its regular sphere of activity and awarded a gold medal to the Director of the Scientific Exhibit. The complete report of the Committee on Awards, giving the names of the recipients of the awards and the titles of their exhibits, was published in The Journal, July 20, 1946, page 1008.

Recommendations.—The Committee on Awards recommended that a new medal be prepared for the Scientific Exhibit. It was felt that the present medal, which portrays the features of Dr. Frank Billings, is not symbolic of the spirit of the Scientific Exhibit. The Committee on Scientific Exhibit confirmed the recommendation of the new medal, and drawings are now being prepared.

Members of the Advisory Committee of the Scientific Exhibit recommended that a public Exposition be held in Atlantic City at the time of the annual session to promote public relations and health education. The Committee on Scientific Exhibit voted to investigate the feasibility of the matter.

Numerous suggestions have been received concerning methods by which a permanent record could be made of the exhibits shown at each annual session. The Committee on Scientific Exhibit voted that photographs be taken showing the detail of outstanding exhibits at the Atlantic City session. Copies will be sold to interested physicians.

At various times there have been requests for a pamphlet containing instructions for the preparation of exhibits. The Committee on Scientific Exhibit favored a pamphlet that would give basic information, and this will be prepared.

Comments and Remarks.—Numerous encomiums were received at San Francisco concerning the value of the Scientific Exhibit as a factor in graduate medical instruction. The credit, of course, goes to the exhibitors who gave so freely of their time and effort, with no thought of reward. The demonstration of an exhibit for a week at the annual session is almost a superhuman task, straining to the limit the energies of persons who undertake it. The Association is in deep gratitude to such persons.

Centennial Celebration.—Plans for the Centennial Celebration at Atlantic City in 1947 have been given much time and study. Close contact has been maintained with the Council on Scientific Assembly and with the sections, each of which has appointed a representative to the Scientific Exhibit. Arrangements have been made for four special exhibits, together with a considerable amount of historical material.

Association Exhibits

The Association Exhibits depict the work of the various Councils and Bureaus of the Association Headquarters on subjects in which those departments are interested. About forty exhibits are maintained for loan purposes, part of which go to medical meetings and other scientific groups, while the remainder are intended for fairs and expositions. During the year several old exhibits were discarded because they were no longer serviceable; others are in the process of repair and rebuilding. Lack of personnel in many of the departments has retarded the building of contemplated exhibits, while the difficulty of obtaining materials has still further delayed the program.

Difficulties in transportation and housing during the abnormal times following the war have interfered with participation in many meetings. A considerable number of requests for exhibits were canceled because of these reasons. During the first eleven months of the year, however, one hundred exhibits were sent to fifty-three meetings in twenty-five states and the District of Columbia. There were twenty-four medical and scientific meetings which used thirty-eight exhibits, each accompanied by a member from the headquarters staff. The Director of the Bureau of Exhibits attended many of the meetings personally.

Fairs and expositions which were canceled during the war opened again in 1946 to a considerable extent. Sixty-two exhibits were lent to twenty-nine local groups in many different states. The opportunity for contact with the public through health exhibits in promoting better public relations is excellent.

Museums

Health exhibits have been maintained in the Chicago Museum of Science and Industry and the Cleveland Health Museum A large group of exhibits was lent to the Dallas Health Museum, which opened in October, and cooperation has been extended to the proposed San Diego Health Museum, which is expected to open in the near future Other museums using the facilities of the American Medical Association include the Newark Museum at Newark, N J, and the Cayuga Museum of History and Art at Auburn, N Y

A question and answer service has been a feature at several of the museums, with the questions answered by mail from the Bureau of Health Education The questions have become so numerous, however, that the service has been temporarily curtailed

Committee on Medical Motion Pictures

In 1945 the Board of Trustees, at the instigation of the Committee on Scientific Exhibit, appointed a Committee on Medical Motion Pictures to make suggestions and report back to the Board At the San Francisco session the Trustees accepted the recommendations and appointed the following committee

Dr W L Benedict Mayo Clinic Rochester Minn Chairman 1947
Mr John G Bradley Director Motion Picture Section, Library of Congress Washington D C, 1947
Dr Dean F Smiley, Bureau of Health Education, A M A, 1948
Mr Ralph P Creer, Bureau of Exhibits A M A, Secretary 1948
Dr Morris Fishbein, Editor, The Journal, 1949
Mr Thomas S Jones, University of Illinois College of Medicine, Chicago, 1949

The Committee has acquired a projection room for reviewing films adjacent to its office on the fourth floor in the headquarters building Reviews of medical motion pictures have been published in The Journal and the source file of films has been expanded

The film library, formerly located in a professional studio, has been brought to the headquarters building, making possible a more efficient handling of films This library is still small, but additions will be made from time to time of films that are of a basic nature The demand for films from medical schools, medical societies, hospitals and other organizations continues to increase

A questionnaire has been sent to all medical schools in the United States and medical societies to obtain information concerning their facilities for showing films and concerning the subjects of films that would be most useful in medical schools and medical societies The response to date is gratifying

The Secretary of the Committee has kept in close touch with other groups interested in medical films and has attended many committee meetings of those groups

Miscellaneous Activities

Numerous conferences have been held on matters pertaining to graduate medical instruction and health education by visual means Visitors have come from all parts of the United States as well as from the Latin American countries and other parts of the world Members of the staff have collaborated with other agencies, serving on various boards and committees

The publications sponsored by the Bureau have continued to be popular Various mimeographed outlines prepared for distribution with exhibits have had a wide circulation

Bureau of Investigation

The number of inquiries recently received in the Bureau of Investigation about "patent' medicines and numerous other forms of quackery shows a substantial increase, and particularly the requests for such information which have come from college and high school students Much assistance is being given to students and others who are doing research work in quackery, and exhibit material is being supplied to teachers and health organizations

Considerable correspondence has been carried on recently with the Post Office Department, the Food and Drug Administration, the Federal Trade Commission, the National Better Business Bureau and its various branch offices, state licensing boards and other organizations regarding individuals and concerns which they and the Bureau are jointly investigating

The Bureau has obtained specimens of two new and widely promoted "hair growers," which the Chemical Laboratory is testing so that the facts on them may be published in The Journal Reports on other types of quackery also are being prepared for publication

In August the Acting Director of the Bureau took part in a television broadcast on "Medical Fakes"

The Bureau is preparing an exhibit for the Association's centennial celebration in 1947.

Bureau of Information

The Bureau of Information, through its service to the returning medical officer, is making a concentrated effort to guide physicians to locate in areas where their services are most needed Through the cooperation of the state medical societies, current listings are available for openings in general practice, specialties and associate positions throughout the country Physicians requesting information regarding a specific area in a state are supplied with summary sheets covering the medical and economic features of the area together with a listing of the communities in that state where there is definite need for a physician

Realizing that rural areas generally are not as well supplied with physicians as urban areas, the Bureau has been working closely with the Council on Medical Service and the Committee on Rural Medical Service of the American Medical Association in developing programs to arouse rural people to an appreciation of the benefits of modern medical science and to stimulate and coordinate the work of the various groups working for better rural medical service

In cooperation with the Bureau of Health Education and the Council on Medical Education and Hospitals, the Bureau of Information gave a television program on rural health problems and the extension to needy areas of more adequate medical care through a better distribution of physicians

The Bureau is working out a cooperative program with the Division of Hospital Facilities of the U S Public Health Service It is hoped that through a coordinated system of rural, city and town hospitals medical service in farm communities will be improved The Hill-Burton law, supporting the survey and construction of hospital, health and diagnostic centers throughout the nation, is one measure aimed at implementing this program in areas where the facilities are unavailable and cannot be supplied through local or state agencies In order to attract physicians into areas where needed, there must be reasonable assurance not only of economic security and satisfactory medical facilities but also of an opportunity to conduct the highest type of medical practice

The Bureau of Information is conducting a survey through local medical societies to determine the conditions and distribution of medical care in the rural areas of the country and the recent movements of physicians into rural areas In developing this survey the Bureau has sent a questionnaire to the state medical societies requesting specific information regarding the medical personnel, facilities and needs of every county in the United States The analysis and results of this survey will be published in The Journal of the American Medical Association

The Bureau is assisting the Committee on Rural Medical Service in arranging the second annual National Conference on Rural Health, to be held on Feb 7 and 8, 1947, in Chicago The meeting will give the farmer and the doctor an opportunity to exchange views regarding many questions which are of vital importance in developing a better health service in rural communities throughout the United States

Respectfully submitted,

R L Sensenich, Chairman
Ernest E Irons, Secretary
Dwight H Murray
William F Braasch
Louis H Bauer
E L Henderson.
John H. Fitzgibbon
James R Miller
C. W. Roberts.

Supplementary Report of Board of Trustees

Dr. R. L. Sensenich, Chairman, presented the following supplementary report, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

REPORT OF DR. IVY

The Department of State of the federal government several months ago requested the American Medical Association to suggest the name of an outstanding medical investigator to represent the United States on an interallied commission to study the medical experiments on human beings carried on by the Nazi government during the war. The Board of Trustees selected Dr. A. C. Ivy of Chicago as the representative. Dr. Ivy went to Europe and on his return submitted a report to the government and a copy to the Board of Trustees. The Board referred the report to the Judicial Council, and it is expected that that Council will report to the House of Delegates its conclusions and recommendations.

MATTERS REFERRED BY HOUSE OF DELEGATES

A number of resolutions and suggestions were referred to the Board of Trustees at the last annual session. In addition, several important items have arisen concerning which the House should be informed.

Resolutions on Inclusion in The Journal of Important Medical Activities in Puerto Rico: Dr. Charles H. Phifer, Illinois, introduced for Dr. Manuel de la Pila, Puerto Rico, under unanimous consent, the following resolutions, which were referred to the Board of Trustees:

WHEREAS, The Medical Association of Puerto Rico is composed of several hundred physicians, of whom the great majority are American citizens and graduates of class A medical schools of the continental United States; and

WHEREAS, This association is affiliated with the American Medical Association and its organization activities and standards correspond to those of the state medical associations of the continental United States; therefore be it

Resolved, That the news and notices of important medical activities in Puerto Rico be included in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in the section of domestic information devoted to the publication of news from the different states and not in the section of news from foreign countries; and be it further

Resolved, That these news items and notices be sent to THE JOURNAL directly by or with the approval of the officers of the Medical Association of Puerto Rico.

The unintentional error has been corrected

Letter from Senator James E. Murray: The Board of Trustees presented a letter from Senator James E. Murray to the House of Delegates at its last annual session. This letter was referred to the Reference Committee on Legislation and Public Relations, which in turn referred it to the Board of Trustees for further investigation and decision as to a reply. The Board has given careful consideration to this communication and is of the opinion that no reply is necessary on account of the change in conditions since the receipt of the letter.

Resolutions on Establishment of Council on History of Medicine: The resolutions regarding the establishment of a Council on History of Medicine, which were referred by the House at the San Francisco session, on recommendation of the Reference Committee on Miscellaneous Business, to the Board of Trustees has been considered and has been discussed with the Council on Scientific Assembly. It was decided to devote one session in the Section on Miscellaneous Topics to the history of medicine at the 1947 annual session.

Resolutions on S. 2143: The Board of Trustees has already had one conference with Senator Taft relative to this bill, and another conference will be held after Jan. 1, 1947. At that conference certain other interested senators will also be consulted.

Review of Fidelity Insurance Schedule: The Board has reviewed the fidelity insurance carried against certain officers and employees, as recommended by the Reference Committee on Reports of Officers at the 1946 annual session, and feels that the present arrangements are satisfactory. For that reason the Board does not think it necessary to make any changes.

Resolutions on Rank of Surgeon General: A committee consisting of Dr. B. R. Kirklin, Chairman, Dr. Hugh P. Smith, Dr. Grover C. Penberthy, Dr. Elmer Hess and Dr. Charles J. Kickham was appointed by the Speaker of the House of Delegates in accordance with the terms of the resolutions adopted by the House at San Francisco on recommendation of the Reference Committee on Miscellaneous Business. The Board of Trustees has made funds available for expenses incurred in connection with this committee's activities.

Bureau of Medical Economic Research: The name of this Bureau has been changed from Bureau of Medical Economics to Bureau of Medical Economic Research. Dr. Frank G. Dickinson, formerly associate professor of economics at the University of Illinois, has been engaged as Director of the Bureau and as economist for the Association.

Financial Report: No report of financial affairs is included in this report. A detailed report is made to the House of Delegates at each annual session.

RESOLUTION ON HEALTH LEGISLATION BENEFICIAL TO THE PEOPLE

At the meeting of the House of Delegate of the American Medical Association in Chicago, Dec. 3, 1945, a resolution was introduced by Dr. Herbert H. Bauckus, delegate from New York, with the title "Health Legislation Beneficial to the People." This resolution proposed that the following principles for a health legislation program be adopted:

1. Establishment in the President's cabinet of a secretary of public health and medical welfare.

2. Encouragement of medical and other scientific research by government grants-in-aid.

3 Federal or state loans or guaranties of private loans for the expansion of hospital and educational facilities.

4. (*a*) Establishment of statewide voluntary nonprofit health care programs.

(*b*) Federal expansion of medical service within such programs.

(*c*) Cooperation with the Veterans Administration.

(*d*) Control of such medical services under state enabling acts.

(*e*) Cooperation and reciprocity between state medical and hospital care programs.

5. Public information and educational services on health.

6. The principle that the functions of government—federal and state—agencies should be to encourage and assist rather than compete with voluntary health insurance plans.

Further, it was resolved that every state medical society be invited to study, adopt and activate these principles on a state level and that they be submitted to the Council on Medical Service and Public Relations of the American Medical Association for immediate consideration as a pattern for a national health program.

These resolutions were referred to the Reference Committee on Legislation and Public Relations, which at that session presented an extensive analysis of the recommendations of President Truman regarding legislation, the constructive program adopted by the American Medical Association and several other resolutions dealing with medical care, and recommended that the House of Delegates of the American Medical Association instruct the Board of Trustees and the Council on Medical Service and Public Relations to proceed as promptly as possible with the development of a specific national health program, with emphasis on nationwide organization of locally administered prepayment medical care plans sponsored by medical societies.

At the 1946 session of the House of Delegates held in San Francisco, a resolution was introduced by Dr. John W. Green of California referring to a resolution which came from the Conference of Presidents and Other Officers of State Medical Associations, which in turn seems to have referred to the resolution introduced by Dr. Herbert H. Bauckus of New York. The resolution introduced by Dr. Green called attention to the fact that the House of Delegates in 1945 had approved a resolution on and adopted principles for a program of health legislation beneficial to the people and that it had referred the resolution to the Board of Trustees of the American Medical Association for further study and appropriate action and asserted furthermore that "no further action has apparently been taken to date." The resolution by Dr. John W. Green resolved that the House of Delegates of the American Medical Association be requested to make its instructions to the Board of Trustees for prompt action specific beyond possibility of misinterpretation. This resolution was referred to the Reference Committee on Legislation and Public Relations, which reported: "Your reference committee is of the opinion that the failure of the

Board of Trustees to take action on the resolution passed in December 1945 referred to was due primarily to the large amount of work presented to the Board of Trustees." It said, furthermore, "Following reorganization voted on Tuesday, we are of the opinion that this subject along with many others will be promptly considered by the proper authorities." At the same session of the House of Delegates Dr. Herbert H. Bauckus introduced a resolution in which he pointed out that the American Medical Association had adopted a ten point progressive program for medical care, that the American Medical Association had taken positive action in placing this program in effect by presenting it before Congress and by implementing its voluntary insurance program in various ways; that the general public is not as aware as it should be of the positive actions of the American Medical Association with reference to hospital construction, diagnostic facilities, infant and maternal welfare, voluntary insurance and health education, and resolved that the American Medical Association be requested to extend its publicity so that the general public will be more adequately informed on the progressive steps of the medical profession and furthermore that the House of Delegates of the American Medical Association request the various state associations to assist in bringing about this publicity. This resolution was also referred to the Reference Committee on Legislation and Public Relations, which reported its pleasure in the resolution and recommended its adoption.

It therefore appears that the delegate from California, Dr. John W. Green, was not aware of the actions already taken by the Association in regard to implementation of its ten point program, but that the delegate from New York, Dr. Bauckus, was familiar with the actions taken and that the House of Delegates in the same session endorsed by one action the extent to which the Board of Trustees had implemented the activities requested by Dr. Bauckus the previous year and in the same session excused the Board of Trustees for not implementing these activities because of pressure of work.

The Board of Trustees would call attention to the fact that many of the activities included in the original resolution by Dr. Bauckus, presented in December 1945, have been accomplished by new legislation or by actions of the American Medical Association in relation to pending legislation. The Board of Trustees therefore presents at this time a report on the various points covered by Dr. Bauckus in his resolution and approved December 1945:

1 The President has not established a secretary of public health and medical welfare in the cabinet. The President did coordinate many medical functions under the Federal Security Administrator, and it is reported that legislation is pending for the establishment in the cabinet of the President of a secretary of health and welfare.

2. The Kilgore-Magnuson bill to encourage medical and other scientific research by government grants-in-aid passed the Senate but failed to receive consideration in the House. Representatives of the American Medical Association appeared at the hearings on this legislation and presented suggestions for modifications of the original measure, most of which were incorporated in the final draft of the bill passed by the Senate.

3. The Hill-Burton bill passed both Senate and House and was signed by the President. Already the board to administer this bill has had sessions, and procedures are under way to make the measure effective. This bill meets the requirements expressed by Dr. Bauckus under point 3 of his original resolution.

4. The Council on Medical Service of the American Medical Association has established standards for voluntary medical care plans and has encouraged the development of Associated Medical Care Plans, Inc., for the coordination of those plans. Many of the states have passed enabling acts which have met with the standards established by the medical profession. Many of the states have already established relationships with the Veterans Administration, and the program for medical care of the veterans has been approved by the House of Delegates.

5. The American Medical Association has established a department of public relations. It has expanded the services of its Bureau of Health Education, it has extended its radio programs, and it is undertaking further promotion of HYGEIA as a means of implementing to the utmost public information and educational services.

6. Apparently the principle that the function of government should be to encourage and assist rather than to compete with reputable voluntary health insurance plans has gained strength from the change in the complexion of the Senate and the House of Representatives, but the Board of Trustees of the American Medical Association and the Council on Medical Service will be continuously watchful to see that this principle is not violated in the development of new legislation.

PUBLIC RELATIONS AND THE RICH REPORT

At the session of the American Medical Association held in San Francisco in July, the Board of Trustees presented to the House of Delegates a digest of a considerable portion of the Rich Report on the public relations of the American Medical Association, together with a report from the Board of Trustees as to certain actions already taken by the Board to make effective some of the recommendations of Mr. Rich and the recommendations of the Board relative to making effective other of these recommendations.

The Board of Trustees did not at that time present to the House of Delegates the second portion of the Rich Report, which dealt with the relations of the American Medical Association to the National Physicians Committee. The complete report is now made available to the House of Delegates.

Several reasons prompted the Board of Trustees to withhold presentation of that section of the Rich Report having to do with the relationships of the Association to the National Physicians Committee and the rest of the report which concerned the functions of some of the councils and bureaus in the headquarters office. In the first place, the major portion of the report was received from Mr. Rich just a few weeks before the date of the annual session of the American Medical Association, and the Board did not have full opportunity to consider it in detail before presenting it to the House of Delegates. In the second place, the proponents of compulsory sickness insurance who had attended the hearings on the Wagner-Murray-Dingell bill before the Committee on Education and Labor of the United States Senate had concentrated some of their attacks on the American Medical Association on its relationship to the National Physicians Committee and had endeavored to break down public confidence in both the American Medical Association and the National Physicians Committee by a series of untruthful and unwarranted statements concerning both organizations and their relationship to each other. The Board of Trustees felt that it would be unwise, in view of the fact that the hearings on the Wagner-Murray-Dingell bill were in progress, to bring this matter before the House of Delegates at the San Francisco session, with the possibility that the public press might by its presentation of the subject and its discussions injure greatly the efforts of the American Medical Association and of the National Physicians Committee as well in combating this vicious legislation. Since that time the hearings on the Wagner-Murray-Dingell bill have been brought to a close without any recommendation by the committee; there has been an election which considerably changes the membership of the Senate and the House of Representatives; there is evidence that the Committee on Education and Labor, which will have such legislation in charge in the next Congress, will be of a different composition and with a different chairman. The hazard which prevailed in June no longer prevails. The Board of Trustees now presents the complete Rich Report to the House of Delegates for its consideration.

These reports should be considered confidential, as they concern the Association's activities only. Many of the recommendations made in the Rich Report have already been put into effect; others are still under consideration.

Attention is called to the fact that this report is copyrighted and cannot be reproduced in whole or in part without permission of the American Medical Association, which is the owner of the copyright.

Report of the Secretary

Dr. George F. Lull, Secretary, presented the following report, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

To the Members of the House of Delegates of the American Medical Association:

The following interim report of the Secretary is respectfully submitted.

MEMBERSHIP

The number of members as of Dec. 1, 1946 was 129,145, an increase of 3,674 since Dec. 31, 1945.

FELLOWSHIP

On Dec. 31, 1945 there were 67,567 names on the Fellowship roster. As it was the wish of the House of Delegates to increase the number of Fellows, a campaign has been carried on during the past few months with this purpose in view. As of Dec. 1, 1946 the roster showed 71,553 Fellows, an increase of 3,986 in eleven months.

The difference between membership and Fellowship is not understood by a great many physicians. Members who are otherwise eligible and who subscribe for THE JOURNAL in many instances think that they are Fellows.

REAPPORTIONMENT OF DELEGATES

It will be recalled that a reapportionment of delegates was effected by the House of Delegates at the annual session in San Francisco. As the wording of section 3 of chapter I of the By-Laws of the Association was not changed subsequent to the decision to hold a supplemental session of the House, it would appear that the reapportionment is not effective until the next annual session in June 1947. The pertinent part of this section of the By-Laws reads "This apportionment shall take effect at the next succeeding annual session. . . ."

PHILIPPINE MEDICAL ASSOCIATION

It was taken for granted at the headquarters offices of the American Medical Association that when the Philippines became an independent nation on July 4, 1946 the Philippine Medical Association automatically ceased to be a constituent of this Association. Its name was removed from the list of constituent state and territorial medical associations, and the names of the members of the Philippine association were removed from the membership roster of the American Medical Association. This matter is reported to the House of Delegates in order that official action may be taken to signify that the Philippine Medical Association is no longer a constituent unit of the American Medical Association.

RESOLUTIONS TO BE PRESENTED TO HOUSE OF DELEGATES

Action taken by the House of Delegates at the San Francisco session provided that resolutions to be presented to the House shall be forwarded to the Secretary and published in THE JOURNAL as far as is possible thirty days prior to the meeting of the House. A number of such resolutions have been received and published. They also have been mimeographed.

Respectfully submitted,

GEORGE F. LULL, Secretary.

Report of Judicial Council

Dr. E. R. Cunniffe, Chairman, presented the following report, adding that a supplementary report would be presented later, and the Speaker announced that he would refer both when the supplementary report was presented:

To the Members of the House of Delegates of the American Medical Association:

The last meeting of the Judicial Council was held in July 1946 at San Francisco in conjunction with the annual meeting of the House of Delegates. At that time certain routine business was transacted. This consisted largely in recommendations of the applications for Associate Fellowship in the American Medical Association of foreign medical missionaries, the consideration of those candidates for Fellowship whose qualifications were questioned and the examination of all correspondence asking advice or opinions concerning the application of the principles of medical ethics to their particular situation. Hearings were also held on the appeal of the Northern Permanente Foundation against the decision of the Washington State Medical Association, which occupied most of the time of the three different sessions. Owing to the delay in the delivery of mail and the failure of the Washington State Medical Association to receive notice of the meeting, each side was allowed part of a meeting, and at a third session both sides appeared before the Council. It was agreed to wait for an answering brief from the Washington State Medical Association. When this brief was finally submitted, it was considered advisable to hold the matter over until the December meeting in order to allow sufficient time for a careful consideration of the material submitted. This appeal will come before the Council in December for further discussion and final disposition. There has been no Council meeting in the interim; hence this report will be brief and consist merely of a statement of the topics to be discussed at its next meeting.

The agenda for the forthcoming meeting will be much the same as usual, consisting of many questions concerning the interpretation of the Principles of Medical Ethics and the examination of numerous plans submitted for approval which involve the relations between ophthalmologists and optometrists. Many of these questions were answered by the Chairman offering his personal opinion, to be reviewed later by the Council. Most if not all of these proposed plans were unethical in that they violated chapter III, article I, section 5, of the Principles of Medical Ethics.

> It is unprofessional to receive remuneration from patents or copyrights on surgical instruments, appliances, medicines, foods, methods or procedures. It is equally unprofessional by ownership or control of patents or copyrights either to retard or to inhibit research or to restrict the benefit to patients or to the public to be derived therefrom. It is unprofessional to accept rebates on prescriptions or appliances, or perquisites from attendants who aid in the care of patients.

Some of these plans also involved the use of combined bills which has always been considered unprofessional and as tending to encourage the division of fees. All these plans will be reviewed by the Council. Its opinion will be sent to the individuals or societies seeking the information, and a more extended statement will be made in the 1947 report of the Judicial Council in regard to the ethics governing the relationship of ophthalmologists and optometrists. Many other inquiries were considered of such importance that no answer was given pending discussion by the Council at the next meeting.

Letters were received from roentgenologists and clinical pathologists asking for advice as to their rights in giving reports on interpretations of films or the results of clinical tests to a doctor who replaces another in charge of the case, even though requested to do so by the patient. Many hold the opinion that the consent of the first doctor who originally referred the case to him must be obtained before releasing these reports. The Council feels that at the request of the patient, preferably in writing, the reports should be immediately sent to the doctor then in charge of the patient. The diagnosis of the patient's ailment is paramount in arriving at the proper treatment to be rendered, and all information which aids the physician should be furnished so that proper treatment or advice can be given without delay. The question whether the contents of the report are to be given to the patient rests with the decision of the doctors who know all the circumstances involved in the situation.

In accordance with the resolution passed by the House of Delegates at the meeting in San Francisco, the members of the Council have under consideration the matter of revising the Principles of Medical Ethics. This proposition is being studied and will be discussed at this and future meetings so that recommendations may be reported at the next annual meeting to be held in Atlantic City in June 1947. As stated at the meeting in San Francisco, any suggestions from members of the House of Delegates will be gladly received and given serious consideration.

It might be advisable at this time, when voluntary prepayment health insurance plans are progressing and when some plans are being offered by others, not connected with the medical profession, in which the formation of medical groups is being encouraged, to discuss the ethics involved in this situation. The Council would therefore remind members of the Association that while solicitation of probable insurers or insurees is necessary to the success of medical insurance plans and is permitted, the solicitation of patients either by individuals or by medical groups is absolutely forbidden.

In the formation of medical groups it is important to bear in mind that the division of income given to members must be in proportion to the value of the services contributed by each individual participant. To divide the income of the group equally after deducting expenses would be in fact the division of fees, which is not only unethical but in violation of the laws of some localities. It might be suggested that each group be required to file its plan for division of income with the local county or state society and that means be devised for insuring strict adherence to the ethical principles as enumerated by the American Medical Association. It might be well to call attention to the section of the Principles of Medical Ethics which covers group practice and which reads as follows

> The ethical principles actuating and governing a group or clinic are exactly the same as those applicable to the individual As a group or clinic is composed of individual doctors, each of whom, whether employer, employee or partner, is subject to the principles of ethics herein elaborated, the uniting into a business or professional organization does not relieve them either individually or as a group from the obligation they assume when entering the profession.

Respectfully submitted,

Edward R. Cunniffe, Chairman.
Lloyd Noland.
John H. O'Shea.
Louis A. Buie.
Walter F. Donaldson.

Report of Council on Medical Education and Hospitals

Dr. H. G. Weiskotten of the Council presented the following report, which was referred to the Reference Committee on Medical Education:

To the Members of the House of Delegates of the American Medical Association:

The major concerns of the Council on Medical Education and Hospitals of the American Medical Association at the present time relate to the reconversion of medical education to a peacetime status. Serious problems are confronted at all levels of professional education in the field of medicine from premedical education to the residency training of physician veterans.

PREMEDICAL EDUCATION

No provision has been made for the deferment of premedical students, and it is unlikely that such provisions will be made. Colleges throughout the country are experiencing tremendously increasing enrolments. Undoubtedly many of these students who are primarily veterans are carrying out premedical studies, although it is not possible to estimate their numbers. Furthermore, it is difficult to estimate what the quality of their work will be, although preliminary observations seem to indicate that the veterans as a group are performing excellently in educational programs.

MEDICAL SCHOOLS

Bona fide medical students in attendance at a recognized medical school are eligible for deferment under the Selective Service System. When the figures for the present freshman class have been assembled they will probably reveal a moderate decrease in enrolments. There are more women than formerly, and there are from 50 to 60 per cent veterans in the freshman class.

All medical schools have abandoned compulsory acceleration, although a few schools permit acceleration on a voluntary basis for selected students. All schools have returned to the annual admission of students. Medical schools in many instances are encountering financial difficulties because budgets were increased during the war, partly on the basis of increased tuition income resulting from the accelerated program, admissions of students every nine months, increased wartime enrolments and the payment by the government of out of state tuition fees in state institutions. Decreased tuition income following the war now necessitates appreciable increases in other support of medical education.

RESIDENCIES FOR PHYSICIAN VETERANS

A major project of the Council since the outset of the war has been to assist hospitals to increase their educational facilities for returning medical officers at the residency level. Compared with 5,256 approved residency positions in 510 hospitals in the year 1941, there are now, as of Oct. 10, 1946, 9,028 residencies in 948 hospitals approved by the Council. This represents an expansion of about 70 per cent in the educational facilities in hospitals. While many returning medical officers have been accommodated by these expanding opportunities, a good many medical officers have been unable to secure residencies. This increase in hospital residencies has tremendously increased the inspection and consultation services and responsibilities of the Council and its professional staff.

Ten of the American boards accept preceptor training in fulfilment of the educational requirements for the Board examinations. This preceptor training supplements residency training in an important manner.

The agreement of the Council with the Veterans Administration concerning the applicability of the educational provisions of the G. I. Bill of Rights to residency training has operated reasonably well except for delays in payments especially to institutions and the small sums paid most hospitals. In essence, this agreement recognizes approved hospital residencies as educational in nature, so that veterans are eligible for subsistence benefits even though the hospital may pay a modest stipend to the resident and even though the resident is provided with maintenance within the hospital. The agreement also provides for a small payment to the hospital—$15 a month per veteran—which may be increased if the hospital successfully negotiates a contract with the Veterans Administration setting forth the costs of maintaining the residency program.

RESIDENCIES IN THE FEDERAL SERVICES

The Council is collaborating with the Army, Navy and Veterans Administration in the establishment of acceptable residencies in selected federal hospitals with a view to improving medical care in those institutions and attracting a higher caliber of medical officer to service in one of these federal divisions.

The program with the Veterans Administration has gone somewhat further than in the Army and Navy. The program of close collaboration of veterans' hospitals with medical schools is proceeding rather favorably and the Council is assisting in furthering this collaboration. An important feature of the forty-third Annual Congress on Medical Education and Licensure, to be held in Chicago Feb. 10 and 11, 1947, will be a round table discussion on residency programs in veterans' hospitals in which medical school deans and representatives of the Veterans Administration will participate.

POSTGRADUATE COURSES

The Council is continuing to publish a semiannual listing of postgraduate courses. These listings have increased in size and diversity of subject matter presented and are contributing materially to meeting the needs of returning medical officers. It is particularly important to note that an increasing number of these courses is being offered by medical schools.

FOREIGN CREDENTIALS OF PHYSICIANS

The serious problem is now being faced of evaluating medical school credentials of physicians graduating from foreign medical schools. It is a policy of the Council to consider for inclusion on its list of approved medical schools only institutions which could be inspected by the Council.

In the past such inspections have not been possible outside the United States and Canada. Recognizing the desirability of some agreement regarding the evaluation of foreign credentials, the Council has organized a committee to study and report on this problem. On this committee there is representation from the Council on Medical Education and Hospitals of the American Medical Association, the Association of American Medical Colleges, the Federation of State Medical Boards of the United States, the Advisory Board for Medical Specialties, the National Board of Medical Examiners and the United States Office of Education. This committee is not yet ready to report its recommendations.

NATIONAL SOCIETY FOR MEDICAL RESEARCH

The National Society for Medical Research was organized because of widespread recognition of the need for a national organization to educate the public to a knowledge of the value in medicine of humane animal experimentation. This society has a permanent secretariat in Chicago and is effectively commencing operations to assist various local groups in carrying out campaigns to inform the public of the vast harm which would be done should various antivivisection proposals be adopted. There has been gratifying financial support for this organization from the medical schools. The Council recognizes the extreme importance of this work in the fields of medical education and research and wishes to urge the full support of the American Medical Association in the efforts of the National Society for Medical Research.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The forty-third Annual Congress on Medical Education and Licensure, to be held in Chicago Feb. 10 and 11, 1947, will be devoted largely to such problems of reconversion in medical education as are discussed in this report to the House of Delegates.

STATUS OF EXISTING MEDICAL SCHOOLS

The approval status of the existing medical schools in this country is unchanged since the last report of the Council to the House of Delegates. Remaining on probation are the Hahnemann Medical College and Hospital of Philadelphia and the two schools of basic medical sciences in North Dakota and South Dakota.

Since July the following medical schools have been visited by the Council's staff for inspection or other purposes:

Medical College of Alabama, Birmingham.
University of South Dakota School of Medical Sciences, Vermillion, S. D.
University of Missouri School of Medicine and the Hospitals of Kansas City, Mo.
University of Vancouver, British Columbia.
University of Washington School of Medicine, Seattle.
St. Louis University School of Medicine, St. Louis.
University of Colorado School of Medicine, Denver.

NEW MEDICAL SCHOOLS

New medical schools are under discussion or in the process of organization in several areas throughout the United States.

The Medical College of Alabama has completed its expansion program from the former school of basic medical sciences to a four year institution and has graduated its first class. This institution has been inspected by the Council staff.

Other two year schools contemplating becoming full medical schools are the University of Mississipi, University of Missouri, University of North Carolina, University of North Dakota, University of South Dakota and West Virginia University.

Entirely new medical schools are being contemplated in Maine, California, Connecticut, New York and Florida. In these developments the Council is lending its guidance lest a low quality of medical education be established in such new institutions as may come to full fruition.

HOSPITAL SURVEY AND CONSTRUCTION ACT

With the passage of the Hill-Burton bill (S. 191) there has been formulated the required Federal Hospital Council as well as an Advisory Board to this Council. The Council on Medical Education and Hospitals is represented on this Advisory Board and will exert its influence in trying to maintain adequate standards of hospital care as well as a wise distribution of hospitals under this law.

REVISION OF ESSENTIALS

The Council presents for the consideration of the House of Delegates revisions of certain of the Council's Essentials. Both the "Essentials for Approved Examining Boards in Specialties" and the "Essentials for Approved Residencies and Fellowships" require clarification, expansion and revision in the light of the tremendous emphasis on hospital residencies and specialty certification at the present time. The Council recommends that the revised Essentials be adopted by the House of Delegates.

RESIGNATION OF THE SECRETARY

Dr. Victor Johnson has resigned as Secretary of the Council, effective April 1, 1947.

APPRECIATION

The Council on Medical Education and Hospitals of the American Medical Association is able to conduct its important work at a high level only because of the continued and enthusiastic support of the House of Delegates and officers of the American Medical Association. The Council deeply appreciates this support and desires in addition to extend its thanks to the many institutions throughout the country for supplying the Council with information and collaborating with the Council in its extensive inspection program.

Respectfully submitted,

H. G. Weiskotten, Chairman.
Harvey B. Stone.
Russell L. Haden.
J. H. Musser.
Reginald Fitz.
Charles Gordon Heyd.
Victor Johnson, Secretary.

Supplementary Report of Council on Medical Education and Hospitals

Dr. H. G. Weiskotten of the Council then presented the following supplementary report, which was referred to the Reference Committee on Medical Education:

The Council wishes to defer consideration by the House of Delegates of changes now being made in the "Essentials of Approved Residencies and Fellowships" until a later meeting of this House.

The Council recommends that there be a change in the title "Essentials of an Acceptable School for Clinical Laboratory Technicians" to read "Essentials of an Acceptable School for Medical Technologists." In conformity with this change in title of the document, the Council recommends changes throughout the text whenever the term "clinical laboratory technician" occurs to read "medical technologist."

As part of this supplementary report, the Council also includes the text of the proposed revision of the "Essentials for Approved Examining Boards in Specialties."

RECOMMENDED REVISION OF ESSENTIALS FOR APPROVED EXAMINING BOARDS IN SPECIALTIES

I. Introduction

The American Board of Ophthalmology, the first of the examining boards in the specialties, was incorporated in 1917. Four additional boards were organized by 1933 (Otolaryngology in 1924, Obstetrics and Gynecology in 1930, Dermatology and Syphilology in 1932 and Pediatrics in 1933).

In 1933 the House of Delegates of the American Medical Association adopted a resolution authorizing the Council on Medical Education and Hospitals "to express its approval of such special examining boards as conform to the standards of administration formulated by the Council" and providing for the employment of "the machinery of the American Medical Association, including the publication of its Directory, in furthering the work of such examining boards as may be accredited by the Council."

In 1933-1934 the Advisory Board for Medical Specialties was organized with representation from each of the approved boards to "act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." The Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties work in close collaboration through joint meetings and frequent conferences.

II. Purpose and Functions of a Specialty Board

An American board in a specialty is organized (*a*) to assist in improving the quality of graduate education in that field, (*b*) to establish minimum educational and training standards in the specialty, in conformity with the general provisions of these "Essentials," (*c*) to determine whether candidates have received adequate preparation as defined by the board, (*d*) to provide comprehensive examinations to determine the ability and fitness of such candidates and (*c*) to certify to the competence of those physicians who have satisfied the requirements of the board, as a protection to the public and the profession.

III. Organization

An examining board in a specialty to be approved by the Council on Medical Education and Hospitals should represent a recognized and distinct specialty or well defined field of medicine. It should be composed of representatives of the national organizations in the field as well as the related section of the American Medical Association. The board should be incorporated.

IV. Definition of Special Fields

The following branches of medicine at present are recognized as suitable fields for the certification of specialists. In each case the symbol employed in designating specialists in the Directory of the American Medical Association is given (A.B.I., and so on). Certain of the boards also certify candidates in subspecialties, as indicated by footnotes:

	Name of Board	Year of Incorporation
A.B. 1.	American Board of Pediatrics[1]	1933
A.B. 2.	American Board of Psychiatry and Neurology	1934
A.B. 3.	American Board of Orthopaedic Surgery	1934
A.B. 4.	American Board of Dermatology and Syphilology	1932
A.B. 5.	American Board of Radiology	1934
A.B. 6.	American Board of Urology	1935
A.B. 7.	American Board of Obstetrics and Gynecology	1930
A.B. 8.	American Board of Internal Medicine[2]	1936
A.B. 9.	American Board of Pathology	1936
A.B. 10.	American Board of Ophthalmology	1917
A.B. 11.	American Board of Otolaryngology	1924
A.B. 12.	American Board of Surgery[3]	1937
A.B. 13.	American Board of Anesthesiology	1938
A.B. 14.	American Board of Plastic Surgery	1937
A.B. 15.	American Board of Neurological Surgery	1940

---

1. Also certifies specialists in allergy.
2. Also certifies specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis.
3. Also certifies specialists in proctology.

V. Qualifications of Candidates

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications:

1. Satisfactory moral and ethical standing in the profession.

2. A license to practice medicine in a state, territory or possession of the United States.

B. Professional Education:

1. Graduation from a medical school of the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association. Candidates who submit credentials from institutions outside the United States and Canada should be required to pass the examination of the National Board of Medical Examiners.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

C. Special Training:

1. A period of special training after the internship, preferably three years, in clinics, dispensaries, hospitals or laboratories approved by the Council on Medical Education and Hospitals and the respective specialty board as competent to provide a satisfactory training in the special field of study. In individual instances specialty boards may grant training credit for work done in preceptorships. Candidates whose special training has been received outside United States should submit credentials satisfactory to the examining boards. Credits for military service may be granted by individual boards.

2. This specialized training preparation shall likewise:

(*a*) include satisfactory graduate training in the basic sciences which is considered by the American board necessary to the proper understanding of the specialty in question:

(*b*) be supplemented by an additional period of not less than two years of training and/or practice in the special field concerned.

(*c*) be evaluated by examinations which should include the basic medical sciences as well as the clinical, laboratory and public health aspects of the specialty.

VI. Establishment of an Acceptable Specialty Board

In considering the organization of an American board in a special field of medicine seeking recognition by the Council on Medical Education and Hospitals of the American Medical Association the procedure is as follows:

A. The application should be presented to the Advisory Board for Medical Specialties. This board in turn shall inform the Council on Medical Education and Hospitals fully regarding the application.

B. The application after being received from the Advisory Board for Medical Specialties will be carefully deliberated by the Council, due consideration being given to the need for a new board, the relationship of that board to the existing boards and the adequacy of the proposed educational programs and available facilities for the preparation of physicians for the certification examinations.

C. The Council will approve new boards only after recommendation by the Advisory Board for Medical Specialties.

D. Official recognition of the board is indicated by listing the specialty in the "Essentials for Approved Examining Boards in Specialties" and indicating certified specialists with an appropriate symbol in the Directory of the American Medical Association.

VII. Residencies in the Specialties

Procedures for considering an institution for approval of a residency for training in a recognized specialty are as follows:

A. The institution should make application to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

B. The Council conducts a survey of the institution to determine whether the residency complies with the Council's "Essentials of Approved Residencies and Fellowships."

C. The Council prepares a report on its findings and conclusions which is submitted to the specialty board concerned for its recommendations.

D. Approval may then be granted by the Council.

VIII. Withdrawal of Approval

On conference with the respective specialty boards or with the Advisory Board for Medical Specialties, the recognition extended by the Council on Medical Education and Hospitals of the American Medical Association to holders of certificates from special examining boards, or that granted to a specialty board, may be withdrawn. Approval may likewise be withdrawn from institutions offering residencies when resurveys by the Council reveal a failure of the institution to maintain a satisfactory educational program.

Report of Council on Scientific Assembly

Dr. E. L. Bortz, Chairman, presented the following report as well as proposed tentative programs of the General Scientific Meetings and sections the official copy of which will be published in the program for the Atlantic City Session, which was referred to the Reference Committee on Medical Education:

To the Members of the House of Delegates of the American Medical Association:

The Council on Scientific Assembly met with the secretaries of the various sections on Sept. 21, 1946 in the headquarters of the American Medical Association. Plans were discussed for the Centennial Celebration meeting in Atlantic City in June 1947.

The General Scientific Meetings will be under the direct supervision of the Council on Scientific Assembly. These meetings will be held Monday afternoon, Tuesday morning and Tuesday afternoon, June 9 and 10. Each meeting will have as its presiding officer a member of the Council. Nine papers will be presented by well known authorities in American medicine on topics of importance to the membership of the Association. The Committee on Centennial Celebration has authorized the Council to invite a distinguished guest to appear on each of the three programs. Each of these men will be assigned a prominent position on the schedule just preceding intermission during the three scientific sessions.

Three panels will be introduced on the program of the General Scientific Meetings. The panels will be on the topics Modern Management of Heart Disease, Emergency Surgery and Antibiotic Therapy. Each of these will be presided over by a distinguished American authority, and assisting him will be experts who will discuss particular phases of the subject. Following these presentations there will be a question and answer period, and finally each panel will conclude with a general summary by the leader of the panel.

The sections of the Scientific Assembly will offer discussions of the first importance in their particular fields by qualified speakers. A historical summary is to be presented by a prominent leader in each field. Each section will have the privilege of inviting a distinguished foreign guest to appear on the program.

The Section on Miscellaneous Topics is divided into three sessions for the Centennial Celebration. One session has been allotted to Allergy, another to the History of Medicine and a third to Physical Medicine. The names of distinguished American leaders have been chosen by the Council to act as chairmen and secretaries, who will be responsible for the details of each of these important sessions.

The Council, with the cooperation of the section secretaries, has drawn up a series of suggestions for each of the speakers appearing on the program, with due emphasis on the type of presentation which is most acceptable to the audience, the manner of showing slides, illustrations, graphs and so forth.

The Council on Scientific Assembly has taken under advisement recommendations for the formation of certain new sections.

Respectfully submitted,

EDWARD L. BORTZ, Chairman.
CLYDE L. CUMMER.
CHARLES H. PHIFER.

Report of Council on Medical Service

Dr. E. J. McCormick, Chairman, presented the following report, which was referred to the Reference Committee on Medical Service:

To the Members of the House of Delegates of the American Medical Association:

PREPAYMENT PLANS

The voluntary prepayment medical care program has progressed rapidly since the House of Delegates met in Chicago in December 1945. Seventeen plans in fifteen states have been started in 1946. This brings the total number of plans to over eighty spread out over thirty-three states, Hawaii and Puerto Rico. In addition thirteen states and the District of Columbia are in various stages of plan development, leaving only two states with no program in progress. The rapid growth in the number of plans will necessarily give impetus to the growth in enrolment. Already enrolment in many of the plans less than a year old exceeds 50,000, and several plans are approaching the 100,000 mark. Last year at this time only two plans had over 250,000 enrolment; at present five of the plans are in this group, with one nearing the million mark and three approaching 500,000. It seems possible that the 5,000,000 goal will be reached shortly after the first of the year.

The Council will continue to concentrate on the overall national picture as it pertains to voluntary prepayment medical care plans. Staff members have met with state committees and assisted in laying the groundwork for prepayment programs. Data and information on plan activities continue to be gathered and reported through the News Letter and individual correspondence. A revision of the brochure on Prepayment Plans is in progress and should be ready for distribution in February.

The technical problem of plan administration will be handled by Associated Medical Care Plans, an organization of the Plans themselves with headquarters in the Council office. Associated Medical Care Plans will work with the Council and will assist the Plans on such problems as reciprocity, sales training programs, standard policies for recording data and other administrative details.

The Seal of Acceptance, as of Nov. 1, 1946, has been granted to twenty-seven medical society approved plans. Using the Seal of Acceptance as a symbol for public identification, the Council hopes to be able to put forth special effort in publicizing prepayment, both to the public and the medical profession.

NATIONAL HEALTH CONGRESS

In the Council's last report to the House of Delegates the suggestion was made that, before setting up a National Health Congress it might be best to survey the status of existing local health groups. With this in mind, and with the approval of the House, the Council is proceeding with the collection of information on state and local health councils. Of the forty-two states answering the Council's questionnaire, nineteen have a statewide health council of some type, twenty have no such organization and three are in the process of forming such a group. A meeting of representatives from existing health councils is planned for early in 1947. From this meeting the Council hopes either to draw up a model program or to set forth specific recommendations for the expansion of the health council idea.

SPEAKERS' BUREAU

A questionnaire concerning the advisability of having a "briefing" course at American Medical Association headquarters has been sent to all the state medical societies. The response has been encouraging. Thirty states have answered the Council's letter. Fourteen already have a speakers' bureau. Twenty-two approve the "briefing" idea, six are not interested and two said they didn't know.

The purpose of the course will be to provide a select group of doctors with sufficient background, information and material so that they may return to their home state and organize county society Speakers' Bureaus. The letters received indicated an interest in factual data, in a supply of material to be distributed to doctors "back home" and in competent instruction in the art of public presentation. In order to keep the group small enough to handle, it may be necessary to have two courses; that is, an east and a west group.

UNITED MINE WORKERS HEALTH FUND

As instructed by the House of Delegates at San Francisco, the Council on Medical Service has followed closely the developments concerning the United Mine Workers Health Fund and the Welfare and Retirement Fund. The principal activity so far has been the survey of conditions existing throughout the bituminous coal mine areas. This survey was made by Navy field teams under the direction of Rear Admiral Joel T. Boone. Representatives of the Council on Medical Service and the Council on Industrial Health accompanied one of the survey teams on a visit to the mine areas to observe at first hand the methods used in making the survey. Representatives have also attended conferences on the survey held by Admiral Boone. The survey recommendations have not been released and any comments must necessarily be postponed until such release is made. A joint report by the Council on Medical Service and the Council on Industrial Health appeared in the Oct. 26, 1946 issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. A supplementary report undoubtedly will be made to the House of Delegates.

TAFT-SMITH-BALL BILL

Early this fall the Council asked each state medical society to submit its suggestions and opinions on the Taft-Smith-Ball bill. At that time it was anticipated that a meeting might be held soon with Senator Taft to discuss the bill. The meeting will be scheduled for some time after the first of the year. The Council is under the impression that Mr. Taft intends to submit this bill to the Senate at the earliest possible moment and therefore wishes to be in a position to relate to him the opinions of the various state medical societies.

HILL-BURTON BILL

At the request of the Board of Trustees, the Council has contacted the state medical societies in an effort to impress on them the importance of preparing a plan of cooperation for putting into effect the provisions of the Hill-Burton bill. When the states have completed the hospital survey and the material has been placed in the hands of the American Hospital Association, the results of these surveys will be utilized in developing a statewide hospital construction plan. What part the medical profession plays will depend on its preparedness and willingness to cooperate with other groups in utilizing funds provided for in the bill. As a service to the states the Council is preparing a statement of principles as a guide to such cooperation and a set of minimal standards for diagnostic clinic facilities. Because of the extreme importance of this program, the Council presents the following recommendations to the House of Delegates:

The importance of the Hill-Burton Hospital Construction bill in the overall program of medical and hospital care should be recognized by all medical societies, state and county.

The medical profession, through its state and county medical societies, should be encouraged to participate actively in plans or programs formulated under the bill.

This participation should include an early review by the state medical societies of the membership making up the advisory council to the state agency charged with the responsibility of carrying out the provisions of the bill to determine the adequacy of medical representation.

This participation should include a positive effort to see that local autonomy is maintained; that facilities are placed only where a specific need for them is shown; that any diagnostic clinic facilities be erected only with the approval of the county medical society in whose area they are placed.

PUBLIC ASSISTANCE PROGRAMS

A number of state medical societies have inquired as to ways and means of organizing medical care programs for recipients of public assistance funds. Little attention has been given to this problem during the past six years, yet it continues to grow in importance. In anticipation of a future downward economic trend, the Council is gathering information and data on such programs. Special attention is being given to the possibility of utilizing existing prepayment plans.

REGIONAL CONFERENCES

The Council is continuing its program of regional conferences but is making every effort to coordinate these conferences with existing meetings. In line with this policy the regional conference in St. Paul was held in cooperation with the North Central Medical Conference on November 10. The conference was attended by about eighty persons and was probably one of the most interesting and informative that the Council has had up to date. The Council has also cooperated with the Middle Atlantic States Public Relations Conference at a meeting held in Philadelphia on November 21. The Middle Atlantic group is a permanent organization resulting from the original Council conferences held in that area and follows somewhat the pattern of the New England States group. Other conferences are planned for other sections of the country.

STUDIES AND PUBLICATIONS

Compulsory Sickness Insurance: The Council is continuing its work on the gathering of information on this subject and, in addition to the brochure entitled "Voluntary Health Insurance vs. Compulsory Sickness Insurance," has printed a set of cards to be used by doctors in giving talks on the subject.

Cooperatives: The Council is gathering information and data relative to the medical cooperative movement throughout the country. This is partly an informative study and partly for the purpose of providing information which can be given to doctors interested in this particular type of medical practice.

Contract and Group Practice: Because of the many requests for information concerning this particular type of medical practice, the Council is planning to bring the original material prepared by Dr. R. G. Leland up to date.

News Letters: Because of the growing amount of material to be used in the News Letters, the Council found it necessary to have them printed rather than mimeographed. This provides for from two to three times as many words and makes a more easily read and attractive publication.

Miscellaneous: Each week many questions arise concerning problems of medical service on which there are insufficient information and data. As a result the Council staff is making a number of studies and compilations which will eventually be published in printed form.

FILM ON PREPAYMENT

The Council has been investigating the possibility of having a film produced on prepayment medical care plans. This film would be of such a nature as to be available to medical societies and various prepayment plans in the carrying on of educational campaigns. Suggestions as to name, length, size of film, continuity and so on have been set forth in a special report to be used in conference with a film producing agency. Tentative cost for such a film seems to be somewhere in the neighborhood of $30,000. The project is being arranged with the Bureau of Exhibits.

CONTACTS

The Council has continued its contacts with many special groups, such as the American Dental Association, National Tuberculosis Association, American Cancer Society and American College of Radiology.

PRIVATE INSURANCE CONFERENCES

During the past few months, the Council has had a series of conferences with representatives from private insurance carrier associations. These meetings were called to discuss problems of mutual interest and resulted in better understanding on each side. In a joint effort to go into more detailed studies of some of the problems, two subcommittees were appointed, one on cooperation and the other on rural enrolment. These subcommittees have recently met in New York and plan further conferences next year.

One of the problems discussed had to do with a simplification of insurance forms. Some time ago the Health and Accident Underwriters Conference and other interested insurance organizations prepared a simplified claim blank to be used by insurance companies in securing medical information from physicians with regard to disability claims. These simplified blanks were submitted for American Medical Association approval and were approved by the Board of Trustees in November 1944. Permission was then sought to imprint this approval on the claim blanks. The Board of Trustees was of the opinion it would be more desirable to have such forms approved by one of the Councils rather than by the American Medical Association and suggested the Council on Medical Service. At the New York meeting of representatives of the American Medical Association and insurance associations the insurance representatives expressed the desire that the Council on Medical Service review, approve and permit the imprint of Council approval on acceptable insurance claim blanks requiring medical data. The Council hesitates to proceed further with this project without specific approval by the House of Delegates.

WASHINGTON OFFICE

The Washington office has new, larger and more attractive quarters at 1302 18th Street N. W. and is now in the process of acquiring proper furnishings. The work should be complete by the time Congress convenes.

The office is engaged at present in reconstructing its filing system so that information and data may be made more easily available to Congressmen and interested organizations. The many and great variety of requests make it necessary to maintain a more voluminous file than was originally anticipated.

The final volumes of the minutes of the hearings on the National Health bill have been printed and are being distributed.

The Director has participated in numerous discussions and round tables on this subject and has assisted the Chicago office in distributing material to students, Congressmen and interested groups.

Every effort is made to be of assistance to individuals and organizations. Expansion of services and personnel is planned to facilitate giving this assistance.

HEADQUARTERS OFFICE

The Council has been provided with almost double its former amount of office space. The personnel has been increased in the past few months from four to eight persons. Mr. Howard Brower, formerly of the state department of insurance of the state of Michigan, and Mr. L. S. Kleinschmidt, formerly of the U. S. Department of Agriculture, Farm Security Administration, are two new assistants. Mr. Brower is working primarily on insurance programs and Mr. Kleinschmidt on community and rural enrolment in prepayment plans. This, in addition to the increase in office staff, gives the Council a reasonable opportunity to carry on the activities assigned to it. The volume of office work continues to increase as the state and county medical societies, the individual physicians and the public discover the services the Council can and will render to them. With this increase has also come a demand for personal appearances on meeting programs and personal attendance at committee conferences. The Council members, the Council secretary and other staff members are making every effort to fulfil this demand.

The Council is prepared at the present time to present to the members of the House of Delegates and to those who are interested a card system for the purpose of aiding and helping those who are speaking on the subject of compulsory health insurance and prepayment medicine. These are just off the press and are available.

The Council would likewise like to call to your attention the booklet called "Check and Double Check" on sickness insurance which has been published under the Public Relations Bureau of the Medical Society of the State of New York. Dr. Dwight *Anderson told me this morning that this booklet is available* for all of you in the lobby. The Council would be well pleased if all members of the House would avail themselves of the opportunity to procure all of these booklets in connection with the Speakers' Bureau venture.

Respectfully submitted,

E. J. McCormick, Chairman.
Raymond L. Zech.
James R. McVay.
Alfred W. Adson.
Walter B. Martin.
Thomas A. McGoldrick.
Roger I. Lee.
H. H. Shoulders.
Louis H. Bauer.
George F. Lull.
Thomas A. Hendricks, Secretary.

Supplementary Report of the Council on Medical Service

Dr. McCormick presented the following supplementary report of the Council on Medical Service, which was referred to the Reference Committee on Medical Service:

The Council on Medical Service at its meeting held Saturday evening, December 7, and Sunday, December 8, arrived at a number of decisions which it felt necessary to add to the original report to the House of Delegates. They are as follows:

NATIONAL HEALTH CONGRESS

With further reference to the National Health Congress mentioned in the semiannual report, the Council has further recommendations to make.

The formation of state or local health councils to meet local needs and enlist the cooperation of other interested bodies has merit. The Council will continue to work on the program and will call a meeting of local health councils and others interested to discuss the value of such councils and draw up a model outline for the formation and scope of such councils.

The Council, however, after much study feels that to set up a National Health Congress as a permanent body is not advisable. Such a body would be bound to duplicate the efforts of, and to a certain extent usurp the prerogatives of this House of Delegates and other bodies of the American Medical Association.

In the opinion of the Council, it would be far better for the Board of Trustees, the Council on Medical Service and other councils of the American Medical Association to call conferences, whenever deemed advisable, on subjects on which the advice and cooperation of other bodies is desirable. In this way different groups could be called on in matters pertaining to their specific fields, and there would not be one set group to consider every subject.

The Council, therefore, requests the House to rescind its previ*ous instructions to the Council to proceed with the establishment* of a National Health Congress.

CHILDREN'S BUREAU

The Council presented a resolution to the House of Delegates at its December 1945 meeting in which a number of recommendations were made concerning the Children's Bureau. This resolution came as a result of a conference on Legislation and Public Relations held some time prior to the meeting of the House of Delegates. The House approved the resolution.

While no request for action was reported back to the Council on Medical Service, we should like to report at this time that one of the principal subjects of the resolution, the transfer of the Children's Bureau to the Federal Security Administration, is now an actuality and that the Council plans to attend a meeting in Washington in the near future, at which time it hopes it may be of considerable assistance in furthering the intent of the resolution.

FILM ON PREPAYMENT

In its regular report to the House of Delegates the Council reported on progress being made with reference to a motion picture on prepayment plans. After further study the Council believes that the project is unpractical and too expensive at the present time.

THE HILL-BURTON LAW

The following special report on the Hill-Burton Law is submitted:

SUGGESTED PRINCIPLES TO GOVERN COOPERATION IN HILL-BURTON LAW PROGRAM

I. Introduction

In extending the best possible medical care under the proposals of the Hill-Burton legislation, consideration has been given to the establishment of diagnostic and health centers in areas where the grouping of medical personnel and facilities will improve the health of the community. The success or failure of the health program under such an arrangement will depend in large measure on the leadership of the profession and the type and quality of medical care given. With this in mind the medical profession, through the Council on Medical Service and the Council on Medical Education and Hospitals of the American Medical Association, has been asked by governmental agencies *to draw up standards governing medical care in these health* centers.

II. Background

1. Action by Board of Trustees: This assignment came as the result of the following action by the Board of Trustees Sept. 19-20, 1946:

> "The Secretary and General Manager reported that he had sent Mrs. Virginia Shuler to Washington recently to consult with representatives of the United States Public Health Service regarding the Hill-Burton bill and that she had reported to the Executive Committee that those with whom she had consulted in Washington were of the opinion that the medical profession could be of great service in the Hill-Burton program if it would set up standards which would combine medical service with the health center idea. The Executive Committee voted to ask the Council on Medical Service and the Council on Medical Education and Hospitals to define a health center and to draw up standards for the rendering of medical care and preventive medical services in a health center.

> "The Board, on motion duly seconded and carried, approved the recommendation of the Executive Committee that the Council on Medical Service and the Council on Medical Education and Hospitals be asked to set up standards." (From Minutes of Board of Trustees, Sept. 19-20, 1946.)

2. Board Calls on Council: Drs. Roberts and Fitzgibbon reported this action of the Board of Trustees to the Executive Committee of the Council on September 18. They indicated the need for a set of basic principles and suggested that these be included in the reports of the Council on Medical Service and the Council on Medical Education and Hospitals to the House of Delegates.

3. News Letter, Vol. III, No. 1, October 18: "Success of Hill-Burton Program Depends on State Action" was the title of News Letter of the Council on Medical Service of October 18, giving suggestions for action and setting forth development of the Federal Hospital Council and the Advisory Committee meetings in Washington.

4. Hill-Burton Bill Provides for Standards: "Sec. 623. (d) If any state, prior to July 1, 1948, has not enacted legislation providing that compliance with minimum standards of maintenance and operation shall be required in the case of hospitals which shall have received federal aid under this title, such state shall not be entitled to any further allotments under section 624."

5. Recent Developments in Washington: Since passage of the Hill-Burton bill, a special committee was appointed by the Federal Hospital Council and a meeting of that committee was held November 7. Following is the text of a release from the Federal Hospital Council dated November 7:

> Declaring that 40 per cent of the counties in the United States have no registered hospitals, representatives of farm organizations today testified to the urgent need for hospitals and health facilities in rural sections of the country.
>
> Meeting as a committee to advise the Surgeon General, U. S. Public Health Service, on rural health problems, they pointed out that the farmers are deeply concerned about raising the health standards of their own communities. They want to know more about the cost of hospitals and how they can be built with federal aid. Moreover, they are interested in a coordinated system of hospitals that will make available modern hospital services to every person regardless of where he lives.
>
> The committee was appointed by the Federal Hospital Council, recently organized to help the Surgeon General administer the Hospital Survey and Construction Act, which provides for a nationwide program of hospital construction. While not all members of the committee were present at today's meeting, the membership includes J. Melville Broughton, Federal Hospital Council, chairman; Ransom E. Aldrich, American Farm Bureau Federation; Joseph W. Fichter, National Grange; Mrs. Gladys T. Edwards, Farmers Union; Miss Elin Anderson, Health Specialist, Department of Agriculture; Dr. M. L. Wilson, Federal Extension Service, Department of Agriculture; Mrs. Agnes Meyer, Advisory Committee to the Federal Hospital Council; Gordon Leith, National Council of Farmer Cooperatives; Dr. Michael Davis, Federal Hospital Council; Graham Davis, Federal Hospital Council, and Dr. Franklin S. Crockett, Advisory Committee to the Federal Hospital Council. William R. Ogg of the American Farm Bureau Association represented Mr. Aldrich at the meeting.

A model hospital licensing act is under consideration by a committee of ten organizations, including the American Medical Association and the American Hospital Association, and copies will be distributed by the Council on State Governments. The need of such legislation is emphasized by the development of the Hospital Construction Program under Hill-Burton legislation.

III. GENERAL RECOMMENDATIONS TO HOUSE OF DELEGATES

1. *General Recommendations:* The Council on Medical Service in its report to the present session of the House of Delegates deals generally with this subject as follows:

> At the request of the Board of Trustees, the Council has contacted the state medical societies in an effort to impress upon them the importance of preparing a plan of cooperation for putting into effect the provisions of the Hill-Burton law. When the states have completed the hospital survey and the material has been placed in the hands of the American Hospital Association, the results of these surveys will be utilized in developing a state-wide hospital construction plan. What part the medical profession plays will depend upon its preparedness and willingness to cooperate with other groups in utilizing funds provided for in the bill. As a service to the states, the Council is preparing a statement of principles as a guide to such cooperation and a set of minimal standards for diagnostic clinic facilities. Because of the extreme importance of this program, the Council presents the following recommendations to the House of Delegates:
>
> The importance of the Hill-Burton Hospital Construction bill in the overall program of medical and hospital care should be recognized by all medical societies, state and county.
>
> The medical profession, through its state and county medical societies, should be encouraged to participate actively in plans or programs formulated under the bill.
>
> This participation should include an early review of the membership of the advisory council to the state agency charged with the responsibility of carrying out the provisions of the law in order to determine the adequacy of medical representation. If necessary, action should be taken by the state medical association to obtain acceptable medical representation.
>
> This participation should include a positive effort to see that local autonomy is maintained; that facilities are placed only where a specific need for them is shown; that any diagnostic clinic facilities be erected only with the approval of the county medical society in whose area they are placed.

IV. SPECIFIC RECOMMENDATIONS

It is recommended that the following subjects receive special consideration:

(1) *Definition of a Health Center:* From the point of view of the medical profession, a health center is an institution in a community which houses the public health functions of a community and which makes available to the medical profession equipment and technical personnel to aid in the prevention, diagnosis and treatment of disease.

In the Hospital Survey and Construction Act the health center is defined as follows: "The term 'public health center' means a publicly owned facility for the provision of public health services, including related facilities such as laboratories, clinics and administrative offices operated in connection with public health centers."

2. *Principles for Operation of Health Centers:* (*a*) Cooperation with County Medical Societies: In any community in which a health center is organized, the advice and cooperation of the medical profession of that community, through the county medical society, shall be sought in order to assure cooperation and efficient use of facilities and services offered. (*b*) Participation of Practitioners: The extent to which each practitioner of a county utilizes the services of a health center shall be determined with the local medical profession. Emphasis shall be placed on the basic principle that diagnosis, treatment and medical care of the individual is not the function of a health center but of the medical profession. (*c*) Emergency Beds for Medical and Surgical Care: Since bed facilities may be required in certain communities for making a diagnosis, such beds shall be available, but patients shall be transferred to the nearest available hospital as soon as the diagnosis and condition of the patient permit. Such beds may also be available for emergency use in such instances as their use may be requested by the physician. (*d*) Radiologic, Pathologic and Other Laboratory Services: The provision of health centers is closely related to the supply of radiologic, pathologic and other special services for use of the general practitioner in areas where these services are not otherwise available. Therefore the decision for the establishment of such facilities in any health center, the remuneration for such services and other details shall be determined by joint agreement of the local public health authority and the county medical society. Principles of relationship between hospitals and radiologists, anesthetists and pathologists approved by the House of Delegates in 1944 should apply (see Proceedings of the House of Delegates of the American Medical Association, 1944, pages 78-79-80). Should it become necessary to establish agencies for standardization of radiologic, pathologic and laboratory services, the representative organizations in the fields concerned should be asked to participate. (*e*) Maternal and Child Health Care: The National Health Program of the American Medical Association states that "every child should have proper attention, including scientific nutrition, immunization and other services included in infant welfare. Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child health centers administered locally with support by tax funds whenever the need can be shown." Child Health Centers may be considered a necessary part of the services of a Health Center. (*f*) Need for Experimentation in Health Center Activities: The Council is convinced that experimentation in the scope and functions of health centers will be required toward evolving satisfactory conduct of such institutions.

(*To be continued*)

Washington Letter

(From a Special Correspondent)

Dec. 16, 1946.

State Health Officers Oppose Public Medical Care Programs

The conference of state and territorial health officers adopted a committee report opposing public medical care programs such as the Wagner-Murray-Dingell compulsory health insurance proposal, because of the shortage of trained medical personnel in the country. The report stated that "neither state health departments nor any other state agencies would be able successfully to carry on such a program at this time." It was revealed that the shortage of administrative professional personnel is so great that 40 million persons in the United States do not have the benefit of a full time health department. Medical care in private practice, it was stated, is also too scarce to permit the extra burden which a public health care program would necessitate to be assumed. Another committee report stated that limited progress had been made in the control of leprosy in the last twenty-five years, and an increase in the number of cases was expected through contacts of servicemen during wartime and through infections brought in by immigrant labor. The 1,000 to 3,000 leprous persons in this country are mostly in the South, the disease being reported to be endemic in the native populations of California, Texas, Louisiana and Florida. Other resolutions urged that the U. S. Public Health Service expand research toward prevention or cure of tuberculosis with increased study of BCG vaccine, that local health departments have special nutrition divisions, that legislation be sought for enrichment of all white bread and flour and the addition of iodine to all table salt and that hospitals expanding under the Hospital Survey and Construction Act consider the need for more maternity facilities.

Hospital Act Explained to Health Officers

Dr. Wane Hoge, chief of the Division of Hospital Facilities, U. S. Public Health Service, explained provisions of the Hospital Survey and Construction Act to state and territorial health officers attending a five day conference in Washington. Federal aid will be given to the states and territories so that they can build enough hospitals to serve all the people. The act provides two funds, $3,000,000 for surveys and planning, and another for construction, totaling $375,000,000, which has not yet been appropriated. The federal government will pay a third and the states two thirds of the costs of surveys based on population. Construction allotments will be based on population and per capita income. New hospitals will be required to serve every race, creed and color.

Congress to Consider Bills to Curb Sale of Sleeping Drugs

Two bills will be introduced in the eightieth session of Congress to curb bootlegging and illegal sale of barbiturates and other sleep-inducing drugs. A bill sponsored by medical and pharmaceutical groups would be all embracing in scope, seeking to control the traffic in such drugs from the manufacturer to the consumer. Providing for control at the state level, it is expected to afford a "near perfect" check on all hypnotic drugs, according to Dr. Augustus C. Taylor, president of the pharmacy board. Another bill, sponsored by the District of Columbia Federation of Women's Clubs, aims to check illicit sales of sedatives at the retail druggist level, but Dr. Taylor says this measure does not go far enough.

Reformatory Inmates to Assist in Research on Common Cold

Inmates of Lorton Reformatory here have volunteered to assist in research being conducted by the National Institute of Health on the common cold. They will be infected with colds in groups of 8 or 10 volunteers, and nasal and throat washings will be used to cultivate the cold organism, believed to be a virus. It is hoped to develop effective vaccines and drugs. Dr. Norman Topping, who developed the serum used against Rocky Mountain spotted fever, will conduct the experiments as part of the $50,000 cold research program.

General Erskine Accuses Communities of Neglecting the Disabled

Major Gen. Graves B. Erskine, U. S. C., chief of the Labor Department's retraining and reemployment administration, informed a veteran affairs conference here that "too many communities have allowed their disabled citizens to depend for their existence on pensions and charity instead of making sure that these persons had the opportunity of taking part in a rehabilitation program." The general declared that he had seen on the streets of Washington "more beggars, most of them disabled, than in any city outside of China." Walter Bura, director of the Veterans Administration Prosthetic Appliance Service, declares that there has been improvement in both the quality and the quantity of artificial limbs being supplied.

Mental Illness Reported to Be Bigger Problem Than Poliomyelitis

Dr. Addison Duval, clinical director of St. Elizabeths Hospital, told parent-teacher groups that "mental illness is a bigger problem than poliomyelitis." He estimated that 1 out of every 25 children entering high school this year could be expected to be a patient in a mental hospital. Dr. Duval said that nearly half of the naval mental patients at the hospital suffering from "gross mental illness" came from homes broken before the child was 13 years old.

Dr. Sterling V. Mead, New Dental President, Honored

Dr. Sterling V. Mead, new president of the American Dental Association, was tendered a testimonial dinner here by 400 well wishers, among them the medical chiefs of the Army, Navy and Veterans Administration and leaders in the dental and medical professions. Dr. Joseph A. Madden, president of the District of Columbia Dental Society, presented a 16 gage shotgun to Dr. Mead, an ardent sportsman.

Miss Frances Perkins Opposes Physical Examinations for Federal Workers

Miss Frances Perkins, U. S. Civil Service Commissioner, has expressed her opposition to physical examinations for federal workers. Under existing laws all new federal employees are required to produce doctor's certificates. The Council of Personnel Administration has worked out a new, improved certificate for this purpose.

Veterans Advisory Group

Dr. Charles W. Mayo of the Mayo Clinic, Rochester, Minn., has been named chairman of a special advisory committee on medical care for veterans, formed by the Veterans Administration with a membership of nineteen nationally known doctors, nurses, social workers and dietitians. The group will give advice regarding policy on all phases of treatment and care in veterans' hospitals and homes.

National Requirements for Student Nurses

Beatrice R. Ritter, director of nursing at Gallinger Hospital, told the Maryland-District of Columbia Hospital Association that 41,000 student nurses would be needed to meet minimum nationwide requirements, but she said that the "home, school and even the church" do not encourage young women to undertake the discipline and sacrifice involved in becoming nurses.

The Closed Head Syndrome

The Army Medical Corps has issued a report on a hitherto unrecognized war malady, a brain condition traced to long exposure to the blast waves set up by exploding shells. The condition found on the tightly enclosed tissue of the brain is termed "closed head syndrome," and its symptoms include headache, ringing ears, deafness and anxiety.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

Southeastern Allergy Association, Atlanta, Ga., Jan. 18-19. Dr. Katherine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

GOVERNMENT SERVICES

ARMY

DEFERMENT FOR EXTENDED INTERNSHIP OR RESIDENCY TRAINING

According to a War Department release interns who complete their twelve month internship between April 1 and July 1, 1947 have been automatically deferred and will not be called to active duty until on or about July 1, 1947. Realizing the need of civilian hospitals for junior residents and/or interns and the desirability of continuing the deferment of as many officers as possible so that they might continue their training, the Surgeon General directed that a study be made to determine the maximum number of deferments that could be effected without too seriously jeopardizing the medical service of the Army.

As a result of this study, it has been determined that the following additional deferments will be authorized to enable officers to obtain residency or extended internship training: 1,200 are to be deferred an additional six months from July 1, 1947 to Jan. 1, 1948; 300 are to be deferred an additional twelve months from July 1, 1947 to July 1, 1948.

In order to place this program into effect, the following actions are necessary on the part of the intern and the hospital which will utilize his services as an intern or resident: The intern is to prepare a letter which the hospital of extended internship or residency will indorse. The latter is to be mailed to the Surgeon General's Office, Attention: Procurement, Separation and Reserve Section, Military Personnel Branch, Washington 25, D. C.

For the 1,200 six month deferments until Jan. 1, 1948, all hospitals will be given equal consideration. Since neither administrative machinery nor adequate hospital data are available in this office to enable the War Department to make equitable allocations of set numbers of persons to the various hospitals, deferments will be granted on the basis of approving those first received until the quota has been filled.

For the 300 twelve month deferments until July 1, 1948, priority will be given to university and teaching hospitals.

The deadline for the submission of requests for all deferments will be March 1, 1947. No request for additional deferment will be considered after this date.

DR. LEO ALEXANDER TO SERVE AS CONSULTANT AT THE NUREMBERG TRIALS

Dr. Leo Alexander of Boston is taking a leave of absence from his practice of psychiatry and neurology in order to comply with the request of the War Department for his service in Europe as a consultant to the Secretary of War. He will be at Nuremberg, Germany, in connection with the trial of major war criminals involved in crimes of a medical and scientific nature, perhaps from three to five months. A secretary who will remain in his office at 433 Marlborough Street, Boston, will be able to transmit any messages to him. Dr. Alexander as an officer in the recent war made extensive study of the criminal medical experiments in certain concentration camps in Germany.

PERSONALS

Lieut. Col. Margaret E. Aaron, who has just completed a tour of duty as deputy superintendent of the Army Nurse Corps, Office of the Surgeon General, will become chief nurse at the Army and Navy General Hospital, Hot Springs, Ark. Colonel Aaron, whose home town in Allentown, Pa., has been a member of the Army Nurse Corps for twenty-eight years.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Joseph E. Bastion

The Distinguished Service Medal was recently awarded to Brig. Gen. Joseph E. Bastion, M. C., U. S. Army, commanding general of Percy Jones General Hospital at Battle Creek, Mich., for exceptionally meritorious and distinguished service from May 1943 to June 1946. Brigadier General Bastion was cited also for outstanding service as an administrator and for the high degree of medical care provided patients under his command. He graduated from Georgetown University School of Medicine in 1906 and entered the service May 5, 1910.

Colonel Idys M. Gage

The Legion of Merit was recently awarded to Col. Idys M. Gage of New Orleans. The citation stated that as surgical consultant, Fourth Service Command, from July 1943 to September 1945, he rendered meritorious service. In the face of unprecedented expansion of hospital facilities, he formulated and carried into effect the surgical program within the Fourth Service Command. This expansion resulted in the creation of many responsibilities for the training of subordinates and for the care of the sick. Dr. Gage graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1917 and entered the service July 15, 1942.

Colonel George P. Denny

The Legion of Merit was recently awarded to Col. George P. Denny of Boston. The citation stated that, as medical consultant, he was responsible for the high standard of medical service in the First Service Command hospitals from January 1944 to October 1945 and that his services were rendered with an unselfish devotion to the welfare of the sick and wounded of World War II. Dr. Denny graduated from Harvard Medical School in 1913 and entered the service June 1, 1942.

Colonel David Henry Poer

The Army Commendation Ribbon was recently awarded to Col. David Henry Poer, M. C., A. U. S., of Atlanta, Ga., for rendering exceptionally meritorious services as chief, surgical service, Newton D. Baker General Hospital, Martinsburg, W. Va., from Oct. 1, 1943 to Nov. 1, 1945. The citation stated that, during this period, Colonel Poer, by his professional skill, judgment, knowledge and unselfish devotion to duty, accomplished his assignment in an outstanding manner, reflecting great credit on his profession and the military service. Dr. Poer graduated from Emory University School of Medicine, Atlanta, Ga., in 1922 and entered the service Oct. 3, 1942.

Captain Lester E. Haushalter

The Bronze Star Medal was recently awarded to Capt. Lester E. Haushalter, M. C., A. U. S., of Milwaukee, for meritorious service in connection with military operations against the enemy in the Netherlands, Belgium and Germany from Nov. 18, 1944 to May 8, 1945. Throughout this period Captain Haushalter, a platoon leader of a station platoon, distinguished himself by his intrepid actions in the treatment and evacuation of wounded personnel under frequent enemy fire. On one occasion when a convoy in which he was riding was subjected to hostile fire, Captain Haushalter, though wounded, exposed himself to enemy fire and moved along the column to render medical aid to other casualties. The exemplary qualities and unswerving devotion to duty displayed by Captain Haushalter reflect high credit on himself and the armed forces of the United States. Captain Haushalter graduated from Marquette University School of Medicine, Milwaukee, in 1934 and entered the service May 18, 1944.

NAVY

MEDICAL ALLIED SCIENCE CORPS

Congressional legislation for a Medical Allied Science Corps is being requested by the Navy Department. Naval Reserve and temporary Regular officers in inactive as well as active status holding doctor's degrees in specialized fields related to the medical profession may apply for transfer to the regular Navy for service in this projected corps. Applications are desired from officers who hold a doctor's degree in one of the following fields: acarology, bacteriology, biology, chemistry, entomology, epidemiology, genetics, malacology, nutrition, parasitology, physics, physiology, psychology, pathology, mammology, malariology, zoology, public health (industrial hygiene), virology and public health (medical statistics).

Officers on active duty who wish to be retained under this program until legislation authorizing the proposed new classification is passed or fails of enactment should submit applications to their commanding officers. Qualified officers on inactive duty should submit applications to the commandant of their home naval district and may then be ordered to active duty at their request if accepted. Age and physical requirements for the new corps are the same as those for the Medical, Dental and Hospital corps.

Applications will be accepted until a closing date is specified. Restrictions as to submission of requests within six months after release to inactive duty or resignation do not apply to this program, which will be conducted in general accordance with the current regulations governing transfer to the regular Navy.

CAPTAIN BROWN AT A. M. A. HEADQUARTERS

Dr. Ernest W. Brown is now on duty at the headquarters of the American Medical Association in Chicago as executive officer for the Committee on Scientific Development of the Council on Industrial Health and in matters pertaining to industrial medical education and toxicology. Captain Brown retired from the U. S. Navy in July 1946 after many years of service, including service on the faculty of the U. S. Naval Medical School in Washington as head of the Department of Environmental Hygiene and as medical director of the New York and Washington shipyards. During the war he was in the office of the Surgeon General of the Navy in charge of industrial hygiene research, chemical warfare medicine and submarine medicine and as liaison officer to the Committees on Industrial Medicine and Armored Vehicles of the National Research Council. Captain Brown graduated from George Washington University School of Medicine and attended Johns Hopkins School of Public Health in 1936-1937. He also has a Ph.D. from Yale University in biochemistry.

PERSONAL

Capt. T. J. Carter (MC), U.S.N., medical officer in command of Naval Research Unit No. 3 was invited to preside on one day of the first Public Health Congress held under the patronage of King Farouk in Cairo, Egypt, the week of November 4. Three of the papers presented at the congress were delivered by officers of U. S. Naval Medical Research Unit No. 3.

NAVY AWARDS AND COMMENDATIONS

Lieutenant (jg) John De Carlo Jr.

The Commendation Ribbon was recently awarded to Lieut. (jg) John De Carlo Jr., U.S.N.R., of Philadelphia for excellent service in the line of his profession as medical officer aboard a United States ship on April 2 and April 12, 1945 during the amphibious assault and capture of Okinawa. On each of these occasions according to the citation, when his ship went to the aid of another vessel which had been hit and left blazing by an enemy suicide plane, as medical officer of the fire and rescue party, he organized first aid groups and directed their participation in the rescue parties at great personal risk from exploding ammunition, gasoline and threatened attack by enemy planes. By his initiative, courage and devotion to duty he contributed materially to the success of this amphibious operation. His conduct and courage throughout were in keeping with the highest traditions of the United States Naval Service. Dr. De Carlo Jr. graduated from Jefferson Medical College in February 1944 and entered the service Oct. 10, 1944.

MISCELLANEOUS

CHANGES IN SURPLUS PROPERTY DISPOSAL PROCEDURES

Sweeping changes in surplus property disposal procedures affecting veterans have been announced by the War Assets Administration, after approval by a committee representing the five leading national veterans' organizations. The changes are:

1. Elimination of unavailable, unserviceable and no demand items from the "set aside list" of goods reserved for sale to veterans exclusively. This action reduced the list from 356 to about 111 items, which include the categories of motor vehicles, fractional horsepower motors, medical, dental and surgical supplies and office machinery, appliances and furniture.

2. Discontinuance of national allocation of such property among the six WAA zones and its offering on a where is, as is basis to cut costs and delays.

3. Acceptance of all certificates after December 9 on a first come, first served basis, regardless of chronological order of issuance.

4. Discontinuance on December 10 of certification for items on set aside list, because of the existing high proportion of certification for items available in the surplus inventory, and a drive to dispose of all of them by February 28, after which date no certificates for such items will be accepted.

In approving the changes, the Veterans Committee requested the director of the WAA Veterans Division to supply data to guide its consideration of the whole subject of surplus property disposal to veterans with a view to legislative recommendations to the next Congress. The committee believes that the changes now being made are necessary in interest of the veterans and the public.

SURPLUS MEDICAL EQUIPMENT ON SALE IN ST. LOUIS

About $8,000,000 worth of surplus medical equipment and supplies are being offered for sale at fixed prices at the St. Louis medical depot, including surgical, dental, professional and scientific instruments valued at about $3,250,000 and x-ray equipment and supplies valued at about $2,500,000.

The equipment, already offered to federal agencies, will be offered to other priority claimants as follows: December 4, 5, 6, 9 and 10, veterans of World War II; December 10 and 11, Reconstruction Finance Corporation for small business; December 11 and 12, state and local governments; December 12 and 13, eligible nonprofit institutions. All other buyers may purchase from December 16 to January 10. This material will be on display at the depot, 412 South 12th Street, St. Louis, until 3:30 p. m. except Saturdays, Sundays and holidays. However, buyers may inspect only on dates assigned for purchase.

Veterans of World War II must be certified at the nearest WAA certifying office. Any individual business or group of small businesses interested in buying should apply to the nearest RFC office for qualification, and an RFC representative will buy for them at the depot. Nonprofit institutions must also be certified and may obtain necessary information by applying to their nearest WAA office. Minimum sales requirement is $25 for veterans and $100 for commercial buyers.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

Charles Goss Appointed Professor of Anatomy.—Dr. Charles Mayo Goss, since 1938 head of the department of anatomy, University of Alabama School of Medicine, University, has been appointed professor and head of the department of anatomy, Louisiana State University School of Medicine, effective February 1. Dr. Goss graduated at Yale University School of Medicine, New Haven, Conn., in 1926.

COLORADO

Laboratory for Study of Toxicity of Various Heavy Metals Under Construction.—A new research laboratory is being constructed in the Division of Industrial Hygiene, University of Colorado School of Medicine, to carry on an investigation of toxicity of various heavy metals, particularly cadmium, and the maximum atmospheric and biologic concentrations which can be withstood without injury to the individual. According to the *Industrial Hygiene Newsletter*, the last real work on cadmium poisoning was done in 1932, results of which have shown that cadmium is stored in the spleen, liver, kidneys and bone. The most common exposure in industry is by inhalation of cadmium fumes and dust. A few fatal cases from cadmium fumes have been reported, but little is known concerning its action when it is administered in small doses over long periods. The industrial hygiene and heavy metal laboratories have been merged into one large, modern and well equipped workroom. Dr. Erving F. Geever, Denver, is the new medical director of the research project with medical students at the University of Colorado as his assistants. It is expected that the immediate phase of the work, cadmium toxicity, will require from two to five years to obtain complete information on all the problems involved, so in a short time the staff will begin the new research.

ILLINOIS

Chicago

The McArthur Lecture.—The twenty-third Lewis Linn McArthur Lecture of the Frank Billings Foundation will be delivered at the Palmer House on Friday evening, February 28, by Dr. Robert H. E. Elliott Jr., department of surgery, Columbia University College of Physicians and Surgeons and the Presbyterian Hospital, on "A Reevaluation of Splenectomy in Thrombocytopenic Purpura, Based on a Twenty-Seven Year Combined Clinic Follow-Up."

Special Society Elections.—At a meeting of the Chicago Tuberculosis Society on October 24 Dr. Hugo T. Cutrera was elected president, Dr. Jacob L. Marks vice president and Dr. George W. Holmes secretary-treasurer. Dr. J. Arthur Myers, Minneapolis, presented a paper at the meeting on "Early Tuberculosis."——Dr. Theodore B. Bernstein has been chosen president-elect of the Chicago Society of Allergy. Dr. William A. Mowry, Madison, Wis., is president and Dr. Edward G. Tatge, Evanston, secretary-treasurer.

Arthur Newitt New Tuberculosis Control Officer.—Dr. Arthur W. Newitt, senior surgeon, U. S. Public Health Service, has been selected to the new office of tuberculosis control officer of Chicago, newspapers reported December 7. Dr. Newitt's appointment was asked by Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, on the condition that he be on leave from the service only long enough to establish the Chicago tuberculosis office. Dr. Newitt has been in public health service as tuberculosis control consultant since 1931 and in the last two years has made control surveys in Chicago, Cook County and New York City.

Research in Atmospheric Environment and Aviation Medicine.—Medical research in atmospheric environment and aviation medicine will be accelerated at the University of Illinois with the completion next summer of a new physical environment addition to the Research and Educational Hospitals at the Chicago Professional College Campus, Polk and Wood streets. Architects are now at work on the final drawings for the new addition, a one story structure with sufficient ceiling height to house a large pressure and temperature controlled chamber, a large psychrometric room and an acoustic laboratory. Cost of the research addition will be $250,000. An additional expenditure of $250,000 will be made for the major portion of the research equipment, which, because of its size, must be installed before the walls of the building are completed.

KANSAS

William Roth to Head Psychiatry Department.—Dr. William Roth, recently released from the U. S. Naval Reserve and formerly of Franklin, Tenn., has been appointed the first fulltime head of the department of psychiatry of the University of Kansas School of Medicine, Kansas City. The training facilities of the department will be enlarged. Dr. Edward T. Gibson, who is also in private practice, will continue as professor of neurology and psychiatry.

MARYLAND

Marcia Noyes Dies.—For the first time in the one hundred and sixteen years' existence of the Medical and Chirurgical Faculty of Maryland, Baltimore, a funeral was held from its quarters, November 27, with services for Miss Marcia C. Noyes, who died November 24 at Eudowood Sanatorium. Miss Noyes last April celebrated her fiftieth anniversary as secretary and librarian of the faculty; for years she lived in a penthouse atop the faculty building, 1211 Cathedral Street (The Journal, April 13, p. 1040).

MASSACHUSETTS

Eye Bank at Massachusetts Infirmary.—An eye bank is being opened at the Massachusetts Eye and Ear Infirmary, Boston, a branch of the Eye Bank for Sight Restoration, Inc. The bank is said to be the second such affiliated unit to be established in the country. In the procedure for persons donating their eyes after death for use in the cornea transplant operation, donors are asked not to make the gift a part of their wills, as a will is not effective immediately. Eyes must be enucleated by at least one hour after death. Because of such medical technicalities it is at this time necessary for the donor to die in a hospital. For this reason the donation is made beforehand on a special blank sent by the eye bank on request.

MICHIGAN

Dr. Coller Honored.—The Detroit Academy of Surgery designates its November 14 meeting "The Frederick A. Coller Meeting" to honor Dr. Coller, professor and chairman of the department of surgery, University of Michigan Medical School, Ann Arbor.

Annual Postgraduate Conference.—The first annual Michigan Postgraduate Clinical Conference will be held in Detroit March 11-14, 1947. The conference, featuring an all Michigan program of physicians and surgeons, will be sponsored by the Michigan State Medical Society with the cooperation of the University of Michigan Medical School, Ann Arbor, Wayne University College of Medicine, Detroit, Wayne County Medical Society, University of Michigan Department of Postgraduate Medicine and the Michigan Foundation for Medical and Health Education. Clinics in Detroit hospitals will be held Tuesday morning, followed by clinical presentations and lectures from Tuesday noon to Friday noon in the Book-Cadillac Hotel. Formal luncheons will be held on March 12-13, and two symposiums will feature Tuesday and Thursday evenings. The banquet is scheduled at the Book-Cadillac Hotel, Wednesday, March 12. The program will be available early in February. Dr. Grover C. Penberthy, Detroit, is chairman of the committee on arrangements and program, and Dr. L. Fernald Foster, Bay City, is secretary.

NEW YORK

Foster Child Care Study.—An extensive survey of the problems surrounding the foster care of about 40,000 children in New York State was begun November 26 by the special committee of social welfare and relief of the Joint Legislative Committee on Interstate Cooperation. A preliminary report on the committee study will be presented to the 1947 legislature.

Street Named for Physician.—A recently completed street north of the Mary Imogene Bassett Hospital, Cooperstown, has been named Atwell Road in memory of the late Dr. Floyd J. Atwell. A memorial resolution was adopted by the village board of trustees recently. At his death Aug. 24, 1940 Dr. Atwell had been head of the obstetric department of Mary Imogene Bassett Hospital and health officer of the town of Otsego for more than twenty-five years. He had been a member of the staff of Bassett Hospital for eighteen years and had served for several years as physician of Cooperstown High School.

Director for New Health Department.—Dr. Frank E. Coughlin, formerly district state health officer, has been named full time health commissioner of Rensselaer County, effective November 1. Dr. J. C. Boland, formerly health officer of Troy, has been named deputy county health commissioner. Rensselaer was the first county in the state to adopt a plan for the organization of a county health district under public health legislation enacted this year. The city of Troy, in approving the plan, under which both city and rural health service will be administered, became the first city in the state to take advantage of the expanded health program. The appointment of Dr. Coughlin was one of the first official acts of the new board (The Journal, October 12, p. 342).

Interdepartmental Health Council.—On October 5 Governor Dewey announced the designation of an Interdepartmental Health Council to consist of the state commissioners of health, social welfare, mental hygiene and education. Hon. Lee B. Mailler, chairman of the New York State Health Preparedness Commission, will serve as an advisory member. Governor Dewey said that the need for the council is clear because public health is a field which touches many phases of community life. The functions of numerous state agencies in addition to the Department of Health are involved. At the recent session of the legislature a vastly expanded program for the integration of public health services, stimulated by the extension of state aid to the localities, particularly to the cities, was initiated. In addition, legislation was passed providing for an all out attack on tuberculosis which, it is contemplated, will require eventually a contribution by the state of $7,000,000 per annum in addition to monies heretofore expended on public health services by the state. The council will formulate and place in operation, through the departments, the necessary implementation for this program. The new council, in addition to coordinating activities already undertaken or to be started this year, will have the function of studying and recommending action on unmet or inadequately covered public health needs. These problems include school health, maternity and school hygiene, the need for expanding psychiatric clinic services, the relocation of physicians, industrial health and accident prevention.

New Research Unit for Mental Diseases.—Henry W. Nissen, Ph.D., since 1939 assistant director of the Yerkes Laboratories of Primate Biology, which are conducted by Yale and Harvard universities at Orange Park, Fla., has been appointed in charge of a newly created unit for biopsychologic research in mental diseases at Rockland State Hospital, Orangeburg. The new unit will be operated under the joint auspices of the Rockland State Hospital, the New York State Psychiatric Institute, New York, and the Council for Research in Social Sciences of Columbia University. Supervising the program of the unit is a scientific advisory committee which is a subcommittee of the Columbia University Council on Research in the Social Sciences. The chairman of the committee is Dr. Dolan D. C. Lewis, director of the New York State Psychiatric Institute; his associates are Karl S. Lashley, Ph.D., Sc.D., Orange Park, Fla., of Harvard University, Robert M. Yerkes, Ph.D., New Haven, Conn., Yale University, Henry E. Garrett, Ph.D., Columbia University, Carney Landis, Ph.D., New York, of the Psychiatric Institute staff, Dr. Russell E. Blaisdell, Orangeburg, N. Y., director, and Mr. Frederic Carnochan, member of the board of visitors, Rockland State Hospital. Elaine F. Kinder, Ph.D., senior psychologist at Rockland State Hospital, is secretary. An administrative committee consists of Dr. Frederick MacCurdy, New York, Dr. Lewis, Dr. Blaisdell and Mr. Carnochan, with Dr. Landis as secretary. The contemplated research will be geared to accomplish three purposes: to achieve meaningful analytic description of abnormal mental processes, to foster integrated studies of abnormal behavior, with appreciation of its more or less regular patterns and sequences and of the interactions of many forces which produce it, and to apply objective, naturalistic methods of experimentation such as are used in comparative psychology. The term "biopsychology" is applied to the project because its technics and approaches will be drawn from those already used with success in the fields of experimental biology and psychology. The work of the unit will be in large measure a cooperative effort of the investigators conducting the experiments and members of the hospital staff who are in charge of the clinical management of the patients.

New York City

Personal.—Dr. John J. Young, Brooklyn, a police department surgeon for sixteen years, has been promoted to the newly created position of deputy chief surgeon of the department. Dr. Eugene H. Pool has been appointed acting medical director for the Medical and Surgical Relief Committee of America.

Site for Cancer Hospital Given to City.—Memorial Hospital for the Treatment of Cancer and Allied Diseases has deeded to the city of New York a site for the construction of a 300 bed hospital for the care of indigent patients with cancer. The city hospital, to be called the James Ewing Hospital in honor of a former director of Memorial Hospital, will cost $3,500,000. The site consists of land on the east side of First Avenue between East Sixty-Seventh and East Sixty-Eighth streets. It is part of the block between these two streets and York and First avenues, given to Memorial Hospital in 1936 by John D. Rockefeller Jr. to create an integrated center for the study and treatment of cancer. The hospital is to be under the supervision of the department of hospitals, which will cooperate closely with Memorial Hospital.

PENNSYLVANIA

Personal.—Dr. Harvey F. Smith, Harrisburg, was elected president of the Harrisburg Chamber of Commerce, October 14. He is said to be the first physician to hold the office in Harrisburg.——Dr. Elmer Hess, Erie, has been appointed a member of the Pennsylvania Board of Medical Education and Licensure, succeeding the late Dr. Paul R. Correll.

Philadelphia

Fraternity Lecture.—Dr. Charles Herbert Best, Toronto, Ont., professor and head of the department of physiology and director of the Banting-Best Department of Medical Research, University of Toronto Faculty of Medicine, Ontario, was the speaker at the annual lecture given under the auspices of the Alpha Omega Honorary Medical Society of the Jefferson Medical College of Philadelphia, November 7.

Chevalier Jackson Honored.—Dr. Chevalier Jackson, professor and head of the department of bronchoscopy, Temple University School of Medicine, was presented with a gold medal on behalf of students at the University of Buenos Aires for his work in training South American physicians. The presentation was made by Oscar Ivanissevich, Argentine ambassador to the United States, during a meeting of the Pan American Association of Philadelphia.

Centennial Meeting.—At the one hundredth anniversary banquet of the Northern Medical Association in the Bellevue Stratford Hotel, December 5, Richard H. Shryock, Ph.D., professor of history, University of Pennsylvania, will compare the outlook of the physician of 1946 with what it was in 1846. The Northern Medical Association, the second oldest medical society in Philadelphia (The Journal, February 23, p. 520), was formed Dec. 5, 1846 to serve the "outlying" sections to the north of the city, including the districts of Spring Garden, Frankford, Germantown and Northern Liberties. Dr. William Wayne Babcock, professor of surgery, Temple University School of Medicine, was toastmaster. Dr. Myer Solis-Cohen, president of the association, and Dr. Maurice S. Jacobs, chairman of the anniversary committee, were speakers. There was a historical exhibition of portraits, letters and minute books. A feature of the occasion was the presentation to those in attendance of a 144 page history of the association, containing portraits and biographies of its eighty-eight presidents as well as other historical articles.

UTAH

Laboratory for Metabolic Disorders.—A grant of $27,750 has been made to the University of Utah School of Medicine for the further support of a study of muscular dystrophy and other hereditary and degenerative disorders. This supplements the grant of $92,000 made last year by the U. S. Public Health Service, Research Grants Division, for the same purpose. With these funds it has been possible to establish at the university a Laboratory for the Study of Hereditary and Metabolic Disorders, of which Dr. Maxwell M. Wintrobe, Baltimore, professor and head of the department of medicine, is director. The activities of this laboratory will be divided among three divisions: the division of biochemistry and physiology, of which Francis Binkley, Ph.D., New York, and Emil L. Smith, Ph.D., are in charge, the division of genetics with Fayette B. Stephens, Ph.D., in charge and the clinical division. The chief of the clinical division, who will also act as assistant director of the study, has not yet been selected. A metabolic ward at the Salt Lake General Hospital forms part of the clinical division The staff of the metabolic ward includes Dr. Virginia Davenport, formerly of the Peter Bent Brigham Hospital, Boston Dr Binkley, who received his Ph.D. degree under Vincent du Vigneaud, Ph D., New York, at Cornell, comes from the Rockefeller Institute for Medical Research, where he was associated with the late Dr. Charles L. Hoagland, New York, in studies on muscular dystrophy and on hepatic diseases. He is now associate research professor of biochemistry and medicine at the University of Utah School of Medicine. Dr. Emil L. Smith received his basic training with Dr. Selig Hecht, Ph D, New York, Columbia University, Max Bergmann, Ph D, New York, at the Rockefeller Institute and Dr L. E. Vickery. He is now associate research professor of biochemistry and physiology at the University of Utah School of Medicine The Laboratory for the Study of Hereditary and Metabolic Disorders is being equipped with the finest modern physical and chemical equipment

GENERAL

Occupational Therapy Editor.—Dr Sidney H Licht, New York, will assume editorship of *Occupational Therapy and Rehabilitation* with volume 26 in February 1947. The journal will continue to issue one volume a year, consisting of six issues Subscription will be $5, and the publishers are the Williams & Wilkins Company, Baltimore 2

Special Society Elections.—Dr. Hal M Davison, Atlanta, was chosen president-elect of the American College of Allergists at its recent meeting, and Dr Leon Unger, Chicago, was installed as president Other officers include Drs. George E. Rockwell, Milford, Ohio, and Willard S. Small, Pasadena, Calif, vice presidents, and Dr. Fred W. Wittich, Minneapolis, secretary-treasurer, reelected.

Group Therapy Association.—The fourth annual conference of the American Group Therapy Association will be held at the Hotel New Yorker, January 10-11 One session will be devoted to a report on "Parallel Group Treatment of Preschool Children and Their Mothers," one to "Research and Training in Group Therapy" and one to "Group Psychotherapy in Private Practice." Additional information may be obtained from the American Group Therapy Association, 228 East 19th Street, New York 3

Narcotic Violations.—The United States bureau of narcotics announces the following:

Dr John C Hattaway, Edison, Ga, pleaded guilty in the U S District Court of Albany to violations of the Federal Narcotic Law, October 14, and was placed on probation for a period of three years

Dr Luther A Nye, Okemah, Okla, pleaded guilty in the U S District court of narcotics, Oklahoma, August 23, to violation of the Internal Revenue Code, and his sentence of five years was suspended and he was placed on probation for a similar period

New Society for Clinical Research.—The Western Society of Clinical Research was organized at a meeting in San Francisco November 1-2. Dr. Gurth E Carpenter, Beverly Hills, Calif, was chosen president, Dr. Mayo H. Soley, San Francisco, vice president and Dr. Helen E Martin, Los Angeles, secretary Among the papers presented at the first meeting were

Dr Lowell A Rantz, San Francisco, Group A Hemolytic Streptococcus Antibody Production in Human Beings Following Immunization
Dr Henry K Silver, San Francisco, Mechanism for the Development of Resistance to Streptomycin
Dr Robert F Rushmer, Los Angeles, Relation of Experimentally Induced Internal Injuries to Lesions Produced in Aircraft Accidents
Dr Norman L Freeman, San Francisco, Direct Measurement of Blood Pressure within Arterial Aneurysms and Arteriovenous Fistulas
Dr Blair V Jager, Salt Lake City, Treatment of Rheumatoid Arthritis with Massive Doses of Salicylates, with Particular Reference to Modification of Plasma Protein Constituents During Therapy
Dr James F Rinehart and L D Greenberg, Ph D, San Francisco, Observations on Thiamine Metabolism

Tropical Medicine Award Goes to Australian.—The American Foundation for Tropical Medicine presented the Richard Pearson Strong Medal, November 26, to Dr. Neil Hamilton Fairley, professor of tropical medicine, London School of Hygiene and Tropical Medicine The presentation was made by Col. Strong, U. S. Army Medical Corps, retired, for whom the medal and award were named and who received them first in February, 1944. The award, together with a $500 cash honorarium, was established by the foundation through a gift by the Winthrop Chemical Company, Inc It is struck in the white metal palladium, which is rarer than gold The citation for the 1947 award declared that Dr Fairley, as brigadier of the Australian Army Medical Corps, who directed the land headquarters medical research unit of the Australian army at Cairns, Australia, obtained information on tropical diseases, notably malaria, scrub typhus and dengue fever that "made possible an earlier termination of the war against the Japanese Empire."

Fellowships in the Medical Sciences.—Fellowships in the Medical Sciences, similar to those which have been administered by the Medical Fellowship Board of the National Research Council since 1922, will again be available for the year 1947-1948. These fellowships, supported by grants from the Rockefeller Foundation to the National Research Council, are designed to provide opportunities for training and experience in research in all branches of medical science They are open to citizens of the United States or Canada who possess an M D or a Ph D. degree and are intended for recent graduates who are not yet professionally established In addition to these fellowships the Medical Fellowship Board administers two groups of research fellowships, made available through a grant from the National Foundation for Infantile Paralysis, Inc The first group, open to applicants who hold either the Ph D or the M D. degree, is for the purpose of providing opportunities for special training and experience in the study of filtrable viruses The second group, open only to graduates in medicine who have completed one or more years of hospital experience in clinical surgery and are planning a career in orthopedic surgery, is designed to provide opportunities for training and research in those basic medical sciences which will be of particular value in furthering progress in the field of orthopedic surgery. A series of fellowships in anesthesiology has been established through a grant from the American Society of Anesthesiologists. These fellowships are offered with a view to fostering a closer union between the clinical practice of anesthesiology and the fundamental disciplines on which anesthesia rests Applicants must hold the M D degree and must have completed one or more years of hospital experience as intern or resident The Medical Fellowship Board of the National Research Council has also under its jurisdiction a number of fellowships of senior grade in internal medicine (Welch fellowships), virus diseases, orthopedic surgery and pediatrics for individuals of proved research ability. Fellows will be appointed at a meeting of the Medical Fellowship Board early in March, 1947. Applications to receive consideration at this meeting must be filed on or before January 1 Appointments may begin on any date determined by the board. For further particulars concerning these fellowships, address the Secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington 25, D C.

Marriages

Kenneth Frederick Eather, Eureka, Nev, to Miss Elizabeth Ann Worthington of Wyncote, Pa, July 27.

William Thomas Parrott Jr., Kinston, N. C., to Miss Fannie Mae Sellers at Waynesboro, Miss, June 19

William Herbert Hall Jr to Miss Helen Mae Moore, both of Jamestown, N. Y, in New York June 15.

Seymour S Rogers, New York, to Miss Dorothy Stewart of Henderson, N C, in Greensboro, September 3.

Harry Penn Harper, Fort Snelling, Minn, to Miss Virginia Louise MacDonald in St Paul recently

Elwood Otho Horne, Worcester, Mass, to Miss Dorothy Louise Schock of Philadelphia August 3.

Frederick C Brush, Shenandoah, Iowa, to Miss Florence Fillenwarth of Charles City, August 30

Henry Bailey Dickens Jr. to Miss Barbara Baker Burgess, both of Fernandina, Fla, September 3

Claude C. Coleman Jr to Miss Jeanette Murdoch Kayhoe, both of Richmond, Va., September 7.

Willis H Hodges Jr, Columbus, Ohio, to Miss Rita Florence Schroeder of Cincinnati June 29.

Mark Baum, Ashton, Idaho, to Miss Charleine Louise Chenoweth of Glendale, Calif. August 10

John Alden Woodcock, Bangor, Maine, to Miss Joan Carlin of Garden City, N. Y, June 15.

Russel W. Weiler, Columbia, Pa, to Miss Carol Bahler of Upper Darby in August.

Raymond N. Brown to Miss Joan Sayers, both of Washington, D C, June 22

Deaths

Roland Chatham Connor ⊕ New York; born in Madison County, Texas, Oct. 8, 1876; University of Texas School of Medicine, Galveston, 1904; delegate to the American Medical Association from the Medical Association of the Isthmian Canal Zone in 1925; life member and past president of the Canal Zone Medical Association; member of the American Academy of Tropical Medicine, American Society of Tropical Medicine and New York Society of Tropical Medicine and a fellow of the Royal Society of Tropical Medicine and Hygiene; interned at the John Sealy Hospital; from 1907 to 1911 physician for the Panama Canal at Ancon, where he was for many years chief of the medical clinic at Ancon Hospital; district physician at Cristobal, Canal Zone, from 1911 to 1914; assistant general manager of the medical department of the United Fruit Company in New York from 1925 to 1931, when he was appointed medical director, serving until his retirement on Nov. 1, 1943; died at the Mayo Clinic, Rochester, Minn., October 2, aged 69.
